Now wait a minute Dave, what about all those Republican capitalist infidels and the offshore accounts? That thread was just great! You're just gonna let it go with this explanation, "please note: (sic) canadian funds?" You could have thrown in some Rooskie Mafia and islamic terroids, and all kinds of stuff that would improve the explanation on why it costs us, the American Taxpayer, more money for them damn Cushcrafts!

Message-ID: <cbvs3o$642@library2.airnews.net>
Source record: 92774

Cut it for a multiple of 1/2 wavelengths.... Use type "f" connectors
and adaptors to uhf or whatever you want to use....

When the transmission line is cut for a multiple of 1/2 wavelength for a
particular frequency, you can put 100 ohms at one end and it will see
the exact impedance at the other end....

I use it on a 40/20 meter cross dipole and it works great and has very
low loss...

4. Re: 40M V Beam question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-01 03:39:20 UTC
From: Bob Wood <bobw@zianet.com>
Message-ID: <10e71rcnm1ldbaf@corp.supernews.com>
Source record: 92775

I want to thank all that replied to my request for information on the 40M V-Beam. I certainly learned a tremendous amount of new things to consider and to try. I did not realize that a V-Beam was numerous wavelengths and that fact alone precludes the installation of such for my current residence. I believe that I will try a better, higher, high quality dipole and then experiment with a horizontal loop and perhaps a phased horizontal array if I can squeeze these within the property lines.

Thanks again to all who shared their time and ideas with me and others monitoring this thread.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.swap,rec.radio.swap

I have for sale the following antennas. This is for PICK UP ONLY from
Beachwood, NJ.

Cushcraft A27010S 10dB Dual Band Yagi. 5 elements on each.
Check out http://www.cushcraft.com/amateur/details.asp?catid=182 for details
on this antenna.

MFJ-1762 6m 3 element yagi.
Details: http://www.mfjenterprises.com/products.php?prodid=MFJ-1762

The MFJ is about 2 - 3 years old and the Cushcraft is about 1 - 2 years old.
Both are in working order and currently assembled. They were taken down when
I had my roof redone and I don't feel like putting them back up.

BEST OFFER. I also have a tripod, a couple of masts and a TV antenna rotator
from Radio Shack that I've used to rotate these antennas.

7. Antenna in mountain

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-01 08:25:18 UTC
From: Bernard Brun <info@bouquetin.com>
Message-ID: <cc0hpg$c28$1@news-reader3.wanadoo.fr>
Source record: 92778

Hello,

I am interested by all experiments concerning the installation and the type of antennas to be used for a station located in mountain. Decametric band and VHF.If possible !

Situation:

French Alps

1.300 meters of altitude.

QTH : 45° 27' 24" North - 6° 41' 56" East

Locator JN35IK

Mask in the north located at 1.000 m. far, altitude 2.300 m.

Mask in the south located at 4.500 m. far, altitude 2.300 m.

Mask in the west located at 3.000 m. far, altitude 1.800 m.

Mask in the East located at 1.500 m. far, altitude 1.900 m.

Mask in western south located at 8.000 m. far, altitude 2.600 m.

Have a large ground, possibility of installing any type of material

Thanks in advance for any suggestion

Thanks for all the help people. Based on the info, I think I'll look
into replacing the handheld (etrex) with an OEM sensor and an external
antenna. Some of the OEM sensors are running under $100.

THanks again!
Dave

Bernhard,

your situation is not oo bad, there are worse scenarios here in Austria.
Aome of my frieds operate from similar locations.

Please keep in mind, that VHF and UHF do verry much reflect from your
surrounding "masks", and you would not believe what is possible to reach
without line of sight.

So any installation of antennas, suitable for the band, will do the job.
There is another pointto be payed attention to: Try to use high gain
verticals, like the ones from diamond, for VHF/UHF. Sometimes the
reflections arrive from different sides at the same time. With a high gain
beam you could miss the most of them, or even cannot tell the direction
where they are coming from.

Please specify the expression "Decametric" in frequency/MHz terms. There are
too many of different bands to be included in this aerea of spectrum.

73 de OE8SOQ
Helmut

BTW, nice place to put up a station!

I believe one thing that drives up the prices on all this mil grade equipment
is requirments for measured drawings so these things can be repaired or
replaced
when in service. For example on ship or sub there is machine shops to fix
things
or fabricate replacement parts.

If they put $ 600 toilet seats in b1 bombers, wonder how much the ones
in the White House or AF-1 cost ?

Although my situation may not be "Alpine," I do live between two
mountain ranges in hilly country (terrain varies 200M through many
river valleys). To the East are the Cascade Range with more than the
average density of Volcanos (think Mt. St. Helens or Mt. Ranier, or
Mt. Hood, or ,,,) which stand in the 4000M area. However, they are
exceptions to the general rule, because the surrounding Cascades are
rather smaller at maybe half to 2/3rds those big guns.

To the west we have the Olympic Mountain Range which are on par with
the Cascades for height. Living between them, my friend often find
they can get better contacts by aiming their beams 180ï¿½ to their
target because there is a small hill in the way and the reflections
off the mountains behind give more than enough signal.

There is also the phenomenon of knife edge diffraction that occurs at
these hill's peaks or ridges. Myself, I live behind a hill that
interferes with my buddy's repeater. I live at 100M above sea level
(Puget Sound), the hill rises to 150M and masks the repeater antenna.
I use RadioMobile software to map the geographic distribution of RF:
http://www.qsl.net/aa7uj/
or
http://www.qsl.net/aa7uj/coverage/10m-1uv.jpg
which is one of several footprints, this one being the 1 ï¿½V
sensitivity service area (shown in orange) for the 10M repeater.

Now, if the concern is with HF bands, then that is probably more a
concern of DX coverage (not suited to RadioMobile as it is principally
line of sight oriented). There I use VOAWIN which is a gargantuan and
very busy propagation modeler. An example of this is found at:
http://www.qsl.net/kb7qhc/propagation/index.htm

The first pass analysis of how much terrain impacts your signal can be
evaluated by simply looking at the peaks. How many degrees above the
horizontal do they rise? If less than 10ï¿½ then no big deal. If more
than 50ï¿½ then you must be living in a cave (most slopes are rarely

steeper than 20-30ï¿½). I must say there are exceptions like deep valleys. Last week I was in the Royal Gorge that is 400M deep and maybe 100M wide.

17. Sensifivity of 2000-ohm Headphones

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-01 19:43:02 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cc1pg6$5c4$1@hercules.btinternet.com>
Source record: 92788

I am writing a program involving an antenna plus two coupled tuned circuits plus a matched simple receiver.

I would like to know, crudely, the audio power input level to 2000-ohm, iron diaphragm headphones for a nice, comfortable, not too difficult listening level. Such as when the phones are used on a crystal and cat's whisker radio receiver.

Such headphones are more sensitive than modern 8-ohm varieties. I have a pair of 2000-ohm headphones but unfortunately no means of measuring power or voltage input.

Just the number of micro-watts please. At what low power input level does speech or music just BEGIN to fade out to a person of normal hearing? Any ideas? I could take the average of a few replies.

Reg, G4FGQ

Odd, I was just corresponding over this very matter recently.

>Such headphones are more sensitive than modern 8-ohm varieties. I have a
>pair of 2000-ohm headphones but unfortunately no means of measuring power or

Then we step into the area of conjecture.

>Just the number of micro-watts please. At what low power input level does
>speech or music just BEGIN to fade out to a person of normal hearing? Any
>ideas? I could take the average of a few replies.

Hi Reg,

This will be have to be done through inference or Web research. As
far as inference goes, I will first state that magnetic speaker
efficiency is extremely poor, but I don't know if this extends to the
headphone implementation. Albeit, between 1 and 10% efficient.

The level of hearing for a child or teen fades out at 1db re
environmental impositions. Technically, in the absence of other
sounds:
1dB re 200ï¿½Dynes per cMï¿½ at 1KHz

0dB = 200ï¿½Dynes per cMï¿½ = 0.1 femtoWatt per cMï¿½

a quiet whisper = 6 femtoWatts per cMï¿½

conversation at 1M = 1 nanoWatt per cMï¿½

Hearing at another frequency such as 400Hz (common sidetone for CW) is
10dB weaker (hearing peaks about 5dB in the 2-4KHz region) and worsens
as frequency lowers.

Hearing loss in the 50-59 Age group for men at 1KHz is about 10dB

Given "hearing" is subjective, a technical response is only as
accurate as the knowledge of these variables (age, sex, frequency,

efficiency).

Hi Reg
I can report using Sennheiser hi impedance dynamic phones to monitor 600 ohm
balanced
broadcast audio signals and you couldn't hear the phones touch the wiring
tree at the TV station.
The signal qualified as a good listening level as I recall.
The phones I used with my crystal set when I was a kid were ceramic.
Surely a Google or two would prove productive.

So the ground jack is needed for matching. I thought that might be the
case.

The 300 ohm feedline was connected to an antenna tuner.

Well I completed installing the antenna and it didn't work for sh*t. So
I tore it down. Chalk one up to experience.

Thanks guys.

I know someone who used to work at Boeing. That $600 toilet seat came about because after the airplane was designed the Air Force came back with a requirement that necessitated (a) a total redesign of the whole interior of the aircraft or (b) narrowing the lav to the point where a stock seat from a 747 wouldn't fit anymore. $600 per seat was cheaper than ripping the whole thing out and redoing it.

The other thing that drives the price up on mil grade equipment is that there's not much of it made. When you are Ford and can count on making 100,000 cars a year you can spend a _lot_ of money on engineering, because it'll be divided by 100,000 when you figure the price of the car. When you're Raytheon and you can only count on selling 100 systems before you need to make something different it would cost the customer many more $$ to engineer the production cost down than it does to just build things stout enough to work without worry.

Hi Bruce, Don't give up just yet. A 25' dipole fed with 300 ohm line and a tuner will work well on 20m-6m. If you could manage 50', then you have 40m. An inverted vee configuration requires only one support. A dipole costs very little and will work great compared to what you were attempting.

Hi Reg, Don't know either, but if you have access to a scope and a signal generator, you could find out what you want. I have these, but not some 2000 ohm phones.
When I was a child playing around with crystal sets, I listened to a 1KW AM station about 1 KM away with a 25' wire, a germanium diode, and a 1000 ohm crystal earphone. The diode drop would be around 250 millivolts, and the listening level would be fine. Thats 250 mv into 1000 ohms. Ther are several crystal radio web sites that may provide more help.

Reg
I used to carry a pair of old military headphones in my kit when building broadcast installations until they were nicked by some ****, I dont think they were as high as 2k but they were not low Z so probably 600ohms and very sensitive, they were handy to listen to one-legged or crossed pairs and crosstalk in circuits etc. I put them across the low impedance output of an audio generator one day and even my aged ears could just hear -60dBm i.e. wrt 775mV (so really dBu in broadcast speak) - that's microphone level! I couldn't vouch to a comfortable level of speech etc but I reckon the answer to your question must lie in the single figure microwatt level for the most sensitive sets.
Hope this helps
John

I get 0.084 u-watts.

Your post inspired me to go to the attic and look for my antique phones again. Found 'em, this time. They are iron diaphragm, engraved on the back "Cannonball Dixie, E.F. Cannon Co., Springwater, N.Y., U.S.A"

I measured the resistance of each can at a little over 1000 ohms. I suspect their Z is mainly R.

I have an old tube type Heathkit audio generator. I measured the voltage at the 0 dB mark with my scope, verified that the voltage division per step is as marked, and cranked it to minus 50 dB, as low as it would go. The sound was clearly audible but not strong. I'm 55 with normal hearing for my age. Even after 700 CW QSOs on Field Day. So anyway, I figured 0.0092 volts rms into 1000 ohms (only driving one can) gives me 0.084 uW. That's amazing.

The phones still showed the effects of my botched attempt to solder on a 1/4 inch stereo phone plug. The fabric covered "wire" is itself mostly fabric--just string with a fragile strand of copper spiraled around it. Not solderable at all. Next time I'll crimp lugs to it instead.

Now it's time to build that crystal set, and/or regen receiver.

This impedance meter is based on SM6MOM's winning entry in the RF Design Magazine contest in 1986. As I pointed out to the then editor of the magazine, the exact same impedance meter was described in the Proceedings of the IRE in 1947. You might want to read the article by the original inventor (I believe his name was Samuels and the title is something like "A Oscillographic Method of Impedance Measurement".)

Thanks Richard
ManOMan - This stuff gets complex. I dont have a VHF sweep signal
generator. I suspect graphic display requires a sweep signal generator.
I once owned a 1947 Proceedings of The IRE. I tossed all my "magazines"
long ago. I wish I could have known. I'd have saved that one (thats a
funny)

The instructions I read for the single frequency method with the 1/8th
lambda coaxs, indicates that the meter reads 80+j12 when the terminal is
loaded with 60+j50. Thats probably OK, but it would sure confuse me.
But, since I beleive the guy who wrote this article is smarter than I am,
I would just like to get some of my confusion cleared up.

In the mean time, I'll go try to dig up "Samuels's" article. Who knows,
maybe I'll learn something.

Jerry

> Jack. PE2JV.

I am using the GPA-50 since about two years and i am very pleased with it, my landlord does not allow to set up a beam and i do not have the space to set up wire dipoles.
The GPA-50 covers 10,15,20,40 and 80 meters but not the WARC bands.
On 10,15 and 20 it uses the included 1/4 wave counterpoises, on 40 the included dipole, shortened with the loading coils and on 80 you need to set up a counterpoise yourself i.e. metal roof or large sheet of chicken wire, the larger the counterpoise on 80 the better.
I have the GPA-50 on a two meter mast at the courner of my penthouse patio, the 1/4 wave radials running to the edge of the roof at an angle of 90 degrees, so i can walk/use the patio beneath them. SWR on 10 to 20 meters is abt. 1:1,2 a little higher at the edges of the bands. I did not cut the radials at all.
The 40 meter dipole is a little tricky since it tends to get "disturbed" by metal close by i.e. metal roof. After setting it up the SWR was infinite. I got it to 1:3 by cutting small pieces from both legs similar. However since i have some metal close by i did not get it below 1:3 but the built in tuner of my radio takes care of that without any problems. I did not expect the dipole working well, however at nighttime and good conditions i am able to work JA with 50 watts from here (North Germany) in CW.
If you have a metal roof try to connect that as counterpoise on 80 otherwise you will have to fiddle with chicken wire or many unbalanced wire counterpoises.
I connected a copper rail running arround the house at the floor of my patio and it works quite well on 80 meters. I tuned the antenna to SWR 1:1 at the middle of the band by adjusting the tip at the top of the antenna. However the range of "good" SWR on 80 is very small so i have to use the tuner of the radio again when QSY'ing on the 80 meter band.
BTW i am located in the 5th floor of the house so the location of the GPA-50 is quite high from the ground.
The antenna gives my quite good results running barefoot only (100 Watts) on DX and with 10 Watts from my IC-703 i can work Europe with reports ranging from S7 to S9+ on 20 meters if conditions are not too bad.

38. QUESTION & REQ: Real Audio Radio Recorder with Schedule/Timer

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-02 10:56:41 UTC
From: Kinsey 6 <kinsey6@somewhere.outthere.com>
Message-ID: <Xns951A46AAA5AB0kinsey6@65.32.1.7>
Source record: 92809

Alright. I don't know what I'm looking for at all, so I figured I would ask all of you. There is this streaming real audio radio show I want to record. It is on weekdays from noon until 3pm, but I have no idea what program I should get to record it on a schedule.

Any guidance would be great. Thanks.

Kinsey6

sure, go for it!

>
> Is there any project, any commercial antenna
> of such length, that allow me to work all band
> 7 - 14 - 21 - 28 MHz ?

just put one up, add a tuner if your radio doesn't have one, and get on the air! it will work fine, cover all bands from dc to daylight, is cheap, easy to use, whitens your teeth while you transmit, and is non-fattening. don't go pay anyone for it, just grab some wire and (horrors upon horrors) build it yourself.

oh, and ignore the inevitable discussion that will follow shortly about why you have to use open wire feeders instead of coax, endless debate about swr, tuning, reflections, losses, matching, etc, etc, etc... stop reading now and go get on the air!

A very good antenna is a half-sized G5RV (7.5m each side). Excellent
results 7 - 28 MHz. Use tuned feeders (any length) and ATU.

73, Peter

If you can make it 11 meters long, about 33 feet, that should get you
14 thru 28 mhz, with the use of 450 ohm feedline and a manual tuner.
If you can stretch it to 51 feet, you can add 10 and 7 mhz.

10 meters = 32.8 feet
11 meters = 36.1 feet

A meter is approximately 3 feet and 3 inches NOT just 3 feet. Those inches
add up after a while.

Test with S G Brown Type F Headphones (display with monospace font)

using sine-wave generator, counter and ac voltmeter.

Frequency 400Hz 700Hz 1000Hz 2500Hz

V (rms)

1.015 ---- ----- ---- Loud

0.340 Loud Very Very Normal
---- Loud Loud

0.100 Normal Normal Normal Quiet

0.030 Quiet Quiet Quiet Very
Quiet

0.010 Very Very Very -----
Quiet Quiet Quiet

0.003 Threshold ---- ---- Threshold

0.001 ---- Threshold Threshold

Perception of loudness by 66 year young man with normal hearing.

I hope this is of some use.

Harry.

Franj,
Can it be done? Yes. Will it be the 'best' of antennas
on all those bands? No. But, if that's all that you can
do, then do it. Anything is 'better' than nothing! Beware
of antenna manufacturor's claims. Taxes are never going down,
and there's no 'miracle' antennas that do everything...
'Doc

don't worry about it... cut it any length you can and use a tuner... it will work all bands from 160m to 6m and probably higher. don't count inches, GET ON THE AIR and have fun!

Reg,

Well, I didn't actually forget - I thought you would know the impedance
of the type F phones. (-:

They appear to be two 2000 ohm earpieces in series, so the impedance is
presumably 4000 ohm.

The DC resistance is 3860 ohm.

I was on the limits of my generator's 50dB attenuation and on the
limits of my voltmeter, so the threshold values are likely to be very
approximate.

We are in the region of 250 pW !

Harry.

This method is a narrow band method. You could sweep over
a narrowband (like an amateur band). What the 1947 article
did was use diode detectors in the square law region connected
to an X-Y scope. The display on the scope is a Smith chart view.
Without a scope, you would use a voltmeter and plot on a
paper Smith chart. I have actually built this and it works,
although it is only as accurate as the squarelaw detectors.

You could also use linear detectors, and use a calculator to
square the number then plot on a paper Smith chart.

I have emailed you a copy of the 1947 paper. (finally remembered
where I stored it).

==========

All dipoles of any reasonable length, inverted-V or not, commercial or home brew, are quite efficient on all HF bands in that they all radiate most of the power which is put into them. The problems lie in loss in the transmission line and the essential tuner.

Erect the highest and longest dipole you can, feed it with open-wire line, use a tuner appropriate for each band of interest and you won't be disappointed.

Or better still, if you can manage it, erect the longest inverted-L you can and feed it at one end tuned against a modest ground system such as a dozen bent surface or shallow-buried radials.

Hi Harry,

You will have to forgive our Brit, computation is a trial, nailing
down specifics difficult, and hearing is not what it used to be.
None of this is terribly difficult, so I am sure Reggie anticipated
your answer, but simply out of Trollish behavior, he prefers to play
naif (a bit beyond the pale at his age however). This is all, of
course, to escape attribution for his intellectual sources for his
upcoming software :-P

You are welcome Punchinello, even if do you rustle this next release's
code under your apron to hide your plagiarism from view.

Reg, G4FGQ wrote:
"I would like to know, crudely, the audio input level to 2000-ohm, non diaphragm head phones for a nice, comfortable, not too difficult intensity level."

First problem is sensitivity of the phones. These vary widely.

Satisfactory reception also depends on competing noise in addition to signal strength. According to the FCC in the U.S.A., you may need 1/2 millivolt for satisfactory reception.

A kilowatt radiated by a medium wave transmitter may produce about 200 millivolts/m at one mile. It depends on antenna and path. Field strength is proportional to the square root of the watts per square meter times 377.

I used to live about 15 mile4s from a 50 KW station. The signal strength at a mile from the station could have been 1.5 volts/ m, and at 15 miles could have been 0.1 V/m. Point is, my crystal set drove a dynamic loudspeaker directly through the output transformer mounted on the speaker. It was clearly audible. Impedance presented to the crystal set was closer to 10,000 ohms at 1 KHz than to 2000 ohms. The speaker and its cabinet were from a battery vacuum-tube set. The audio power may have been less than a microwatt, but as a kid my ears were acute.

My 2nd edition GE "Transistor Manual" has 2000-ohm headphone amplifiers with 2 milliwatts maximum power output.

Chinese stereo headphones claim 20-20KHz response, 32-ohms impedance, 100dB/1mW sensitivity, 140 mW rated input, 400 mW max. etc. Much of this spec. is target and untrue. Wide variations exist between samples of these phones claiming similar specs.

The GE book is believable. Class A power output is from the familiar. First formula says maximum power is 1/2 the product of the peak voltage and peak current. Load resistance is then the peak voltage divided by the peak current. So, Load resistance=Epk squared/2Po

When GE prints the circuit of a 2 milliwatt amplifier driving 2000-ohm phones, I believe it works.

Best regards, Richard Harrison, KB5WZI

GET
> ON THE AIR and have fun!
>

I agree that he should just get on the air. But those inaccurate conversions although only inches result in feet in antenna dimensions and is not insignificant. If one wants to get into resonant antennas, it becomes particularly important. Even at 10 meters, the difference is 2.5 feet for a full wave length antenna between using a conversion of 3 feet per meter versus 3.25 feet (3 feet 3 inches) per meter. For a half wave dipole it would be 1.25 feet. At 160 meters the difference climbs to 40 feet for a full wave loop and 20 feet for a dipole.

These differences can be important even with a tuner. We've got an 80 meter loop cut for the voice segment. My internal tuner will NOT tune it for the CW portion so I must use my external tuner. If we had based the length on using 3ft/meter rather than the 3.25ft/meter, it would have been too short to tune on even the voice portion of the band.

Reg,

I (also) have a very old pair of Philips Hi-Fi headphones.

The spec is given as 2 x 600 ohm (they are stereo phones).

Sensitivity is given as 112dB at 1mW.

I assume this means 112dB above the Threshold of Hearing (1pW per
square metre) at 1mW in.

A power input of 1nW would given a sound level of 52dB, which would be
at a normal (comfortable) level.

A power input of 1pW would give a sound level of 22dB, which would be
at whisper level.

These headphones would appear to be more sensitive than the S G Brown
type F headphones.

Harry.

==========

Frank, the exact impedance of the high impedance line doesn't matter at all. You don't even need to know what its impedance is. Line loss is small just because it has a high impedance.

Any line where the pair of wires are spaced apart more than 25mm will be satisfactory. Wire spacing can change along its length without any bad effects. The only effect will be a change in tuner component settings.

If you are unable to purchase a line then it is not difficult to make. You can make the stuff in less time than it takes to order and deliver from a manufacturer.

Use 1.6 or 1.3 mm diameter wire. Space the wires 50 mm to 100 mm apart. There are many ways of fixing the wire to the ends of rigid plastic spacers. The distance between spacers along the line can be anything from 100 to 200 mm. Construction depends on your judgement of what weather conditions, wind velocity, etc., the line will have to withstand and the time in months. Failure due to flexing in the wind can be a problem.

Frank,
Any antenna you put up is not forever. So, start small. At this pont in the sunspot cycle there is not much propagation on 10 & 15 m. A wire 10 m long is resonant at very close to 14.2 MHz. Feed it in the center with 50 Ohm coax, and get on 20 meters. As an inverted V, you should be able to trim the SWR to well below 1.5:1.

Hi guys.

I decided to try the Extended Double Zepp, thanks to some advice I got from the contesting.com archives. I put up two of them, one for 18 MHz (70' long, 60 high) and one for 21 MHz (60' long, 50' high.)

One of the items mentioned was that "the tuned feeder is not necessary, if you just run balanced line all the way to a tuner."

This is how I have always run my wire antennas anyway, I am very big on ladderline, and it has always served me well in the past. However, what I am finding is that I have a pair of very nice antennas; they outperform anything else I have on 20m and above, except that there is no directionality whatsoever!

Could this be from the way I am feeding them? Any advice appreciated.

The 2 meter band is about 146 megaHertz. GPS uses a frequency of
around 1.2 gigaHertz.

Not many antenna designs can handle a 10:1 frequency range, especially
with such high frequencies.

There are external antennas available for some GPS units, but most
have a built in antenna,

There is a type of GPS receiver, sometimes called a "mouse" type,
which has no display or processor iteself, but must be attached to a
laptop or PDA in order to work.

Happy trails,

Possibly, but I doubt that it would be a good one. GPS uses
frequencies roughly 10x as high as a 2-meter rig. The 2-meter antenna
would probably not be resonant on GPS frequencies, and if it is of a
helical design or has a base-loading coil it might very well be a
lousy antenna on the GPS frequency (the coil or helical winding
could act as a low-pass filter, blocking the GPS signal).

Its radiation pattern would probably have a lot of lobes pointed in
weird directions, and I suspect that the GPS signal from any given
satellite would be subject to a great deal of fading and jitter as the
vehicle and antenna move.

GPS receivers tend to use small "patch" antennas, etched into a piece
of PC-board substrate. These most often have a fairly uniform,
low-gain sensitivity pattern in the skyward direction.

Also, the GPS antennas separate from the GPS receiver are usually
"active" ones - they have a preamplifier very close to the antenna,
and boost the signal before it's fed down the coax to the receiver.
Losses in a typical RG-8X or RG-59 thin coax are quite high at 1.5
gigs, and the already-weak GPS signal could tend to be lost if not
preamplified.

The other problem with using a 2-meter antenna as a GPS antenna would
be that you'd need some pretty good form of switching, to keep the
input of your GPS receiver from being blown out when you keyed up the
2-meter transmitter.

I'd guess that it was a standalone receiver. Even back then, there
were GPS receiver the size of a pack of playing cards (or smaller),
which plug into a PC's serial or USB port.

Not only is the frequency range vastly different, (tho, the SWR LOSS's would mean quite little extra loss from coax , in receive mode for the GPS) BUT- the GPS uses a psudo omni directional antenna , read that an immitation of an isotropic , relative to ALL angles, and polarizations)! (remember that , with a verticle, a direct overhead signal will be next to invisible)! and it take something like 4 satellites, to calculate where you are (these are moveing FAST! Altho, think there is a ham antenna was designed for such purpose- but SPENDY! Jim NN7K

Harry Whitfield wrote:
"Sensitivity is given as 112 dB at 1 mW. I assume this means 112 dB above the Threshold of Hearing (1pW per square metre) at 1 mW in."

That looks OK to me. My handy "Science Answer Book says:
Hearing starts at zero decibels. 10 units is a tenfold increase. The sound made by leaves rustling is often 10 decibels. Office noise level is typically 50 decibels. A pneumatic drill = 80 dB. A riveting machine = 110 dB. A jet takeoff at 61 m (200 ft.) measures 120 dB. Noise above 70 decibels harms hearing. At 140 dB, noise is physically painful.

Acute hearing is sensitive. More so in some other species.

In a previous posting I may have appeared naive saying I believed GE produced a circuit for a 2 milliwatt 2000-ohm headphone amplifier. But I have additional evidence of the adequacy of 2 milliwatts. For many years I worked at a radio station where we kept a pair of crystal phones near the audio patch panel. These, because of their extremely high impedance, could be bridged across any program line with no significant effect. Program lines are usually adjusted to a zero VU level (1 milliwatt into 600 ohms) or 0.775 volt on program peaks. Magnetic phones produced about the same audio output with 0.775 volts as did the crystal cans. The difference is only in the circuit loading of the 2000-ohm magnetic phones on a 600-ohm circuit. Point is, one milliwatt is plenty loud in headphones. I know from listening.

Best regards, Richard Harrison, KB5WZI

The L1 GPS frequency used by us common folks is 1575.42 MHz, a little
more than 10x 2 meters. Another minor problem is that GPS antennas (and
signals) are circularly polarized (easy to do with a patch or with
helical designs). If at the end of a cable, most GPS antennas (such as
patches) have built-in amplifiers (and filters), and expect +5 VDC
(current limited) supplied on the cable to run the amp.

You could try to use your 2m antenna at GPS frequencies by putting a
high-pass filter between it and the GPS receiver; I don't think it's
going to work very well. Already mentioned is the fact that vertical
antennas have a sharp null directly overhead. Circular polarization is
another issue. Gain (loss) at L1 is going to hurt.

But give it a try and let us know how it works!

No. At best, the 2 meter element will be an endfire longwire at GPS frequencies.

I don't know the reason you wish to run both on the same antenna, but I also needed the same antennas on my car. I have a Garmin III Plus as the input to APRS in the car. I use a suction cup mounted external antenna for the Garmin GPS which is about (from memory) 2.5 inches wide, 1.5 inches deep, and .4 inches thick. It works very well mounted to the lower center of the windshield on my Jetta. I run through a duplexer into a trunk mounted Comet UHV for the 2m APRS antenna.

Nice!
http://www.remote.arrl.org/news/stories/2004/06/28/2/?nc=1

One thing to note...
They tried notching out amat bands (without success)
but were going to leave all the other HF bands trashed.

You may be getting interaction between the two antennas. And you
wouldn't be trying to share the same feedline, would you?

I tend to remember that a meter is 39.37 inches. Makes for an extra step,
but fewer numbers to remember.

John, MW1FGQ wrote:
"I used to carry a pair of old military headphonees in my kit when building broadcast installations until they were nicked by some ****."

Several models of telephone receivers were used in WW-2, including the TS-10 (sound powered) unit. This was probably the most efficient transducer except for the R-13 and other resonant models designed for morse code reception. The HS-33 with its leather-covered headband is the model I saw most often. I don`t remember it being particularly sensitive but it did have pretty good fidelity.

I seem to recall seeing the most valuable patent ever issued by the U. S. Patent Office. It`s the Alexander G. Bell telephone patent. The microphone was dynamic, not carbon, so his receiver had to be sensitive as the instrument was sound powered.

I used to carry around a surplus TS-10 unit in my kit. Although sound powered, it is not sharply resonant. The fidelity is not too bad. Aboard my ship in WW-2, I had a spare TS-10 unit wired with an attenuator and connected to the ship`s entertainment and information line. There was an almost 24-hour music feed from radio or records. We had a V-disk transcription library too. Nobody complained and the zero dBm level was plenty loud if I turned up the attenuator. Little electrical power is needed for considerable acoustical power when using the right transducer. As long as I kept the movie projector running, the skipper would let me get away with about anything.

I guess I'm right. Nothing but bile, venom and hate. You can't think, probably as a result of the leftist indoctrination you received in the public schools instead of an education. I'll answer just one of your "points". Where does it say that I (or you) should be provided health care at government expense? I and my whole extended family have been providing our own health care for decades now, with the help of our employers. We trade our skills and knowledge for money and benefits. Work is great thing. You should consider getting some. Better yet, you should start a business. That will get your head on straight faster than anything.

Russ

83. butternut and 17 meters problem

Newsgroup: rec.radio.amateur.antenna

Greeting!

I am having problem tuning my new Butternut HF9V vertical on 17 meters.. My antenna is ground mounted 60 feet from the house or anything else. I have 40 radials surface mounted just under the grass... The swr on all the other bands is about 1.4 to 1 or less, but on 17 meters its 2.4 to 1 causing my ft-847 to fold back power.. Though! the high swr, I am still able to make contacts to Europe and other DX on the band with little effort with less than a 100 watts... I do have a MJF-259 analyzer and still have problems.. I have spent hours at attempting to get a lower swr

Any Help would be appreciated

Thx in advance ` 73

WA3YMM

Easy solution - use a matching network (tuner) on 17m. What does the
MFJ-259 say the 17m impedance is looking into the feedline. How long
and what kind of feedline?

With the completion of this trial, I am of the opinion that there is a unique opportunity for amateur radio to cooperate with the power companies and build a bridge to solve and/or resolve the RF mitigation challenges.

I am also of the opinion that it would be a profound mistake to take a standard alpha or beta test--successfully completed earlier than expected-- and interpret it as some 'victory' to 'kill BPL'. This is far from it; and if some vocal, minority of hams take that approach, it will only render their voice as irrelevant in the ongoing process. It will, again in my opinion, look very bad for ham radio.

Time to build bridges into the future. Surely you agree.

Reg:
Not an absolute , but just indicitave of the sensitivity of these- is when used as a tone finder on telco cables (with a butt set, or "buttinski"), and applying a tone on a pair at -10 dBm-- Ground one conductor of the butt set, and hold the other clip in your hand. just use your finger (body resistance), and run the pairs one conductor at a time, and the tone will be heard on all the pairs, tho the LOUDEST tone is on the pair tone sent on! This is an old telco installers trick, and gives a great indication of just how sensitive these high impedence headsets really are! As info, Jim NN7K

>Is this feed, suitable for ham purposes (transmission power: max 100W) ?

It's certainly useable. For a short run, the losses would probably be acceptable (20 gauge conductors aren't great but aren't terrible) especially when it's dry and in new condition. In wet weather it's going to be lossier than ladder line or open-wire line, although at HF frequencies this additional loss may not be significant.

If you try to use it with an antenna which is badly mismatched for the frequency, the high SWR on the line might lead to significant heating of the line at 100 watts - this will depend on the impedances involved. I have no idea whether the foam dielectric in the cable would be adversely affected by the heat buildup at the high-current spots on the line, or might arc over at the high-voltage spots.

> I could take the average of a few replies.

Hi All,

Perhaps an exercise useful to approximate within 2 or 3 orders of
magnitude.

The problem with measuring against the physiological response (aka
hearing, seeing, and the other senses) is that we "own" the estimate
as a personal expression of our integrity (how could be wrong?).
Problem is that such measurements are invariably fraught with the
widest error spread imaginable.

For a simple correlation (based on the cool, calm, detachment of
instrumentation) I noted the specifications for my speakers (Pioneer
vintage mid 70s) which describe they are capable of producing a SPL
(sound pressure level) of 92dB @ 1M @ 1 Watt. They also supply a
chart of relative sensitivity across the band of 20-20000 Hz, Harmonic
distortion, Impedances (room and coil). The published variation shows
that premium equipment wanders to considerable degree (Z, nominally at
10 Ohms varies from 5 Ohms to a peaked 40 Ohms). Hence nearly every
audio specification is set at either 1KHz or 400Hz and those
practitioners know full well not to abstract them throughout their
hearing range (which they also know full well varies with even much
wilder swings).

Let's take that same 92dB @ 1M @ 1 Watt and compare to the several
reports of hi-Z headsets. The first translation is of course against
application. Headphones encompass far less distance than 1M. I will
arbitrarily assign a path link of 1cM for the ear canal and re-specify
my Pioneer speakers to 112dB @ 1W (basically with the ear pressed next
to the speaker cone).

If I simply derate the power to achieve to 2dB above the threshold of
hearing (110 of that same 112dB) the power is similarly derated to
1W / 10ï¿½ï¿½
or
10 picoWatts

>The spec is given as 2 x 600 ohm (they are stereo phones).
>Sensitivity is given as 112dB at 1mW.
-whew!- 2dB level at 10 femtoWatts

Harry offers the wildest variation. His first SG Browns are
25 times worse than my speakers
however his Philips Hi-Fi headphones
3 orders of magnitude better than my speakers!

Hence, as an average, response to this question spans roughly 7 orders
of magnitude.

As the quality of unzipped (and unrevealed design) software goes, such
a spread could easily satisfy anyone, even boys in their treehouse
with a string and dixie cup telephone system.

What accounts for this ENORMOUS swing of response to a simple
enquiry? The human element of owning what amounts to "dead

reckoning." The perception of sound is individual, not absolute. Through the survey above it also suffers in reporting too few variables. In other words, just what dB level satisfies such qualities as "just hear" "clearly audible" "good" "fine" and any other subjective qualifiers? The nearly 7 decades of variation cover roughly half the hearing range between threshold and pain - 140dB. Obviously if we trimmed 40dB from each end, the middle zone of the remaining 60dB suddenly becomes "average" listening levels for "someone."

Well, I hope you guys enjoyed this tour of the fantastic improbability of human sensation rendered to a fixed number. ;-)

For 1.5 inch copper pipe - check any of your larger plumbing distributors
(size is used for sewer/waste pipe)
PVC has replaced it usage over the last 30 years -- in some localities.
With the amount of home building in the Carolinas
- this should not be to difficult to locate. However, you may be surprised
at cost (copper commodity prices have been quite high - lately)

Andrew -

You should investigate the usage of a mobile antenna, such as the GPSx
Survivor by Antenex, 2000-205 Bloomingdale Road Glendale Heights, Illinois
60139
http://www.antenex.com/

GPSx Survivor - Model GPSDVHF
This very durable antenna features a 26dB gain active ceramic patch GPS
receive antenna with a durable black chrome plated, shock spring protected
VHF • wave antenna in one complete package.
The real advantage of this antenna is its mechanical integrity. This dual
band antenna is constructed with a fully potted heavy wall resin housing, a
one-piece solid brass mounting stud, a large diameter tapered shock spring
and a tunable 0.100" diameter 17-7ph stainless steel radiator for VHF. All
of this makes it perfect for heavy equipment asset tracking and monitoring.

It comes complete with 14 feet of RG174 terminated with an SMB connector for
GPS and 14 feet RG58A/U terminated with N connector. It is mounted through a
5/8" diameter mounting hole and secured with an included heavy stainless
steel jam nut.

Sounds like a good solution.

However, I would not call that a dual band antenna, but two different
antennas mounted in the same package.

How is the active GPS antenna powered?

Dear Tam:
During WW2 the value was changed. UK, Canada, and USA each had a
slightly different value. Became a problem with things having threads.
I think that the Canadian value won. Now: one inch is 25.4 mm
exactly.

The subject is rather vague, as others have pointed out.

The teensiest hint on exactly what you want, and/or what you plan to
use it for, would probably get you more useful responses. This
includes quantity.

McMaster-Carr at www.mcmaster.com can ship you a large variety of
metal stock, including various grades of copper.

There are size limits on what they can ship, and they may not be the
least expensive option for larger quantities, but always simple, with
a wide selection, and fast.

And Kerry will pay for it!! Yeah, sure!!
43 million americans don't have health care. It costs about $10,000 per person per year for health care. So, 43 million times 10,000 = 430 BILLION $$$$$$$$$$$$$. That's more than his wife's fortune!

You can't think straight... probably because of your nazi-like
indoctrination
from the republican. Where does it say taxes will be taken from me to
rebuild
a digusting Islamic government half way across the world. I'd rather have my
taxes pay for health care for every American. Means tested. If you are

rich you
pay more. If you are poor, its free. The poorest bum on the street
doesn't have
any better access to the system than the richest person in the country.
Its right
and you know it. But I'm sure a selfish person like yourself could never
see it
the right way. Everyone pays something out of their pocket if they are able.

Richard Clark wrote:
"It just occiurred to me that my mock response of 43 is as good as
any-....."

Almost, but the subject does have reference points though "threshold of hearing" has almost as many values as there are people, or maybe more than the population, depending on conditions.

Keith Henney in his 1938 "Principles of Radio" says:
"Loudspeakers in general are notoriously inefficient - the best in common use is not over 30 per cent. Most of them are less than 5% efficient."

In the years since 1938, efficiency has not made a big improvement. Headphones are likewise inefficient and vary widely from sample to sample.

Harold Ennes says in "Broadcast Maintenance":
"A level of 0.0002 dyne per square centimeter is considered to be the threshold of audibility."

According to Fig 1-4 in the Ennes book, this is an intensity of 0 db. A sound pressure of 0.00002 dynes per square centimeter is a sound intensity of -20 dB, while 0.002 dynes per square centimeter is +20 dB.

Broadcast microphones are said to produce a power output of from -50 to -65 dBm at a sound pressure of 10 dynes per square centimeter.

Sound transducers are said to vary by 15 dB in sensitivity among those of the best quality, and that is at a particular reference frequency and without variations which depend on the location of the source with respect to the microphone above. Then think of a comparison of individual response curves of sound transducers. It`s somewhat chaotic.

A description of headphone performance can be made which can be useful to compare performance despite all of the problems. Microphones and headsets of WW-2 are charted in "Electrical Communication Systems Engineering" published by the War Department in April 1945. Useful characterizations can also be made of other sound transducers.

Best regards, Richard Harrison, KB5WZI

Message-ID: <904dab11.0407032116.3e99d646@posting.google.com>
Source record: 92691

Hi,

I've presently installed the best antenna that I could. I made major miscalculations on my layout.

Turns out that maximum height of trees and building is 20 feet. Balcony
rail height is 12 feet.

The best I could presently do is make a balanced wire in the horizontal plane.
It is basically a dipole whose endpoints are 15 degrees apart rather than 180.

Length of one arm is 40 feet, the length of the other arm is 45. It is number 30 kynar insulated wire supported by 12 inches of nylon cord at at each end off balconies across the lawn. Altitude is 12 feet. I am in a desert climate,
violent weather is almost unknown except for 2 months out of the year where we have monsoons. By my experience, number 30 wire is too thin for the air to push very or to be affected by the rain.

I think this will have to be a receiving wire, i don't believe I have the necessary take off angles for dx.

Any suggestions for improving this situation?

Thanks,

The Eternal Squire

>to the speaker cone).
>
Should be 132dB @ 1W - which, of course, does nothing to the spread of
reported responses. However, even this correction is fraught with
error because it presumes a free field (violated at the ear canal
where it becomes a pressure field) - well, such are the pitfalls of
computing with sound.

For those seriously interested in the Physics of sound, vibration, and
its measurement, the preeminent authority in this field is in Denmark
with Brï¿½el and Kjï¿½r:
http://www.bksv.com/pdf/Sound_Intensity.pdf
who offer microphones that can pick up sound 40dB below the threshold
of hearing.

By the way, one of the interesting points about their anechoic
chambers is mention that if you sat in one, you could hear your heart
beating (and this not just simply the blood pumping through veins near
the ears - which are self canceling anyway).

It's probably going to work like crap on 7 MHz. Consider buying
a GOOD tuner, and also try tricks like feeding the coax
common mode (shield and center tied together) to run your
ten meter dipole as a top loaded vertical wire. This assumes
you can run the coax or balanced line in a straight run away from
existing structures. You'll also need a good ground or a few
on the ground radials for the antenna to work against when
it is being run as a vertical. Don't be afraid to experiment.

Pete

true enough. unfortunately, my budget won't support sending them $89.95
PLUS S&H.

if I had the design schematics, I'd have one built locally for the cost of
materials.

You can also download the PDF for the assembly manual. I'd
think you could get a good headstart homebrewing one from
there....

Hi All,

I will be moving into a house with a salt water canal in the backyard.
The lot is about 100 feet wide on the canal with nothing but ceramic tile
surrounding a pool...NO open Ground just a few palm trees surrounded small
squares of mulch.....
I am looking for any ideas for an antenna....to cover 80-10 .....

Anybody have experience with salt water near by???

Thanks

Steve

132. Building a 51 mhz inverted V - feedpoint question....Help!

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-04 16:14:58 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <2kqonqF56rujU1@uni-berlin.de>
Source record: 92703

When I first moved into my 3rd floor (top floor) apartment 11 months ago, I wanted to get back on HF ASAP. So, I rounded up all the wire I had and made a 153'4" dipole with an SO-239 chassis mount at the feedpoint. I strung the antenna around this red brick building and was on the air with my FT-817 and LDG Z-11 tuner in no time. The antenna tuned easily even down to 1.8 mhz but I was running a straight piece of rg-58 coax from the feedpoint to the tuner and I was getting a lot of RF in the shack.

I posed this problem to this group and was told to coil several turns of coax at the feedpoint. I looked around for a form and found a 2-3/4" diameter
glue bottle. I wound 9 turns of the existing coax around this form, then used
superglue to hold the turns together. Came out rather nice and worked very well!

A few months later I was told I might get better results with more turns on a
larger form. I grabbed another spare coax piece and this time used a CD 50 pack round case for a form (5-1/4" dia, 12 turns). This worked even better!
In April I finally got permission to put an antenna or support no higher than
10 feet high on the roof of this apartment building as long as I did no permanent
changes. I used a Rat Shack vent pipe mount and 2 - 5 foot masts to hold up the top of a Van Gorden 134' "All Bander" antenna. Nice landlord, eh?

With the All Bander in place and after several weeks of comparing performance
of it with the old antenna, I took down the old antenna and wrapped it up and
threw it in the closet. Now, I'm running a FT-857D and a LDG Z-100 tuner.

I thought I'd like to build a 6 meter SSB/CW inverted V dipole out of the leftovers from the old antenna/coil/coax setup in the closet. No sweat but I am
concerned if that a 2-3/4 inch, 9 turn choke would be ok on 50-51 mhz at 50w?

I'm too impatient to wait so I'm gonna start building now but I 'd very much like to hear your opinions - I can always make changes and even build more coax assemblies with coils wound on one end with different turn diameters and more or less turns as I have several coax assemblies in the closet that are'nt
getting used right now.

Anyone have an opinion for # of turns and what diameter would be best for
50w @ 50-51 mhz SSB/CW? BTW the antenna will be taped to a large
window on the 3rd floor, facing east & about 3-4' from my PC and radio gear.

Hi Ken,

Simply think proportionality. What worked best at which band? Scale
by band. The choke is principally designed as an inductor. More Z,
better. However, as with anything in nature, there are capacitances
that come into play. For these chokes they aid in the sense of
offering a resonance that further increases Z. However, such
capacitances, at some frequencies, become series resonant
opportunities and the game is gone.

The standard advice for 6 to 8 turns of 6 to 8 inch diameter work well
for mid-to-upper-HF, smaller is indicated by the rule of proportions,
but not very much smaller. Using ferrites offers a more controlled
approach and becomes a matter of selecting the right material, visit:
http://bytemark.com/products/content0.htm
specifically (for discussion of materials and properties):

Gary -

Correct, this is 2 antenna is one mounting - which is important for some mobile installations (e.g. public safety and utility vehicles) AND since the desired characteristics of each antenna are entirely different.

For GPS at 1.5 GHz -- the antenna pattern needs to see the entire sky. Why? GPS receivers require a minimum of 4 satellites in view to perform a position lock - and the constellation of GPS satellites are always moving (orbit) in you visible sky. Look at any new car (e.g. 2004 Honda Accord with Navigation option) - you will see the GPS antenna housing at the center of the hood back - for maximum sky visibility.

For 2 meter mobile - the desired antenna pattern is toward the horizon. This is why 5/8 wave antennas are popular - since their pattern at the horizon is superior to almost all other antenna types (e.g. 19" 1/4 wave or 38" 1/2 wave antennas).

Power to the antenna is an excellent question. There are 2 types of GPS antennas - passive and active.

"Passive" GPS antennas (also called substrates) do not include a Low Noise Amplifier (LNA) and are best suited to GPS applications requiring a short distance, 1 inch to 3 feet, between the GPS receiver and antenna. Passive antennas require an LNA on the GPS receiver (such as the GT+ "R4" part number series) or mounting a separate LNA close to the RF input connector of a receiver that does not include an on-board LNA (such as the GT+ "R3" series and the M12).

"Active" GPS antennas include a built-in Low Noise Amplifier (LNA) which provides sufficient gain to overcome coax cable losses while providing the proper signal level to the GPS receiver. This LNA requires power from the GPS receiver to operate -- the GPS receiver antenna connector (just like the older style UHF TV pre-amps from the 1970s).
The GPS voltage standard use to be 5 volts -- BUT this was recently been changed to 3.3. volt by most manufacturers.

In order to prevent damage to the GPS receiver or antenna -- YOU MUST MATCH the GPS receiver and antenna.
Some antenna manufacturers can handle both voltages - BUT NOT ALL.

The company that I obtain my GPS supplies form is Synergy Systems, LLC in San Diego. They are the largest distributor of Motorola GPS receivers - and have been a supported of TAPR, Amateur Radio APRS usage as well as educational experimenters (GPS for Scholars program).
http://www.synergy-gps.com/

I always check their excess inventory sale for inexpensive GPS items (Acrobat PDF)
The Oncore units are OEM boards and require a TAC-2 or equivalent interface board for operation

Maybe a vertical antenna?? At least you should have a good ground
there. Here in the high desert, "ground" is something sometimes as
hard to find as a tree for antenna support.

141. Mechanical Help needed on 32 foot vertical

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-04 19:37:54 UTC
From: Da Shadow <DAS@cat.net>
Message-ID: <m0ZFc.12837$z81.1499@fed1read01>
Source record: 92712

For Field Day we homebrewed a 32 foot vertical out of five swimming pool poles. Secured to a six foot tripod with spikes in each tripod leg.

The radiator was a 32 foot length of zip cord.

Four radials (zip cord) were used at about the 10 foot level drooping down.

SWR was 1:1.5 to one across the 40 M band

Used it on 15M as well with SWR less than 2.5 to one.

Antenna worked well across country on both bands. West coast to east coast.

Next year I would like to refine it by replacing the swimming pool poles with aluminum tubing (6 foot sections) where each section fits into the previous one. Figure I will need 6 sections to allow for 4 inches inserts. Then hose clamp them. May have to double up and use double wall tubing.

Trying to figure what diameter to start with at the bottom. Greatly prefer NOT to use guy wires.

Another problem is insulating the 32 foot radiator from the tripod. Maybe a 5 foot section of plastic pipe PVC ???

Maybe I am better off to use the swimming poles as they didn't fall down for 24 hours (;-)

Ideas appreciated

>poles. Secured to a six foot tripod with spikes in each tripod leg.

I have used a vertical supported by a 33' fiberglass push up pole. (Kanga and
MFJ among others sell these, about $90) The radiator was #14 stranded wire.
Required no guys, clamped the bottom to a 4' wooden fence with a couple of
conduit clamps. One year I used my deck railing and conduit clamps.
This vertical can easily be raised and lowered by 1 person. I have also used
this as the support for an 80-10m inv. vee, and two of them for 80-10m dipole.
It took one person (me) 20 minutes to get the 80-10m dipole in the air.
I know this didn't exactly answer the question you asked, but it might give
you some options.

>Then hose clamp them. May have to double up and use double wall tubing.

Another alternative: I've been told that it's easy to purchase
sections of aluminum tubing with built-in snap-together fittings.
They're sold in the concrete/cement portion of building-supply stores,
and are used to create the long handles for concrete "floating"
(smoothing) tools.

I picked up a half-dozen poles like this at a local surplus-metals
dealer. They'd make a very decent mast, and probably a decent
vertical (although I'm not sure just how reliable an electrical
contact exists between adjacent sections when they're snapped
together). They're 1" in diameter and have an overlap area of about
2".

>Trying to figure what diameter to start with at the bottom. Greatly prefer
>NOT to use guy wires.

I'd encourage you to always use at least one set of guys on an
impromptu vertical of this size. It really wouldn't take all that
much wind force at the top to render your tripod unstable... and
having a 32-foot aluminum pole come down on somebody's head would
really spoil your Field Day.

>Another problem is insulating the 32 foot radiator from the tripod. Maybe a
>5 foot section of plastic pipe PVC ???

Sure, that'd work. PVC cap on the bottom, notch out a spot a couple
of inches above the bottom to run a cable-and-clamp through, and you'd
be good to go.

Check with Texas Towers (http://www.texastowers.com). They have a program
for computing such. You will be surprised at the large diameter necessary
to avoid guy wires. It wasn't worth it for me. It's super easy to guy using
black dacron string/rope.

> Another problem is insulating the 32 foot radiator from the tripod. Maybe a
> 5 foot section of plastic pipe PVC ???

I wrapped the bottom aluminum tubing section in PVC pipe and U-bolted it
to a 2x4. Perhaps something like that would work for you.

148. Strange Antenna in old 73 magazine ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-04 22:08:03 UTC
From: Jeff <jeff_164@hotmail.com>
Message-ID: <8d%Fc.7124$LT3.277012@news.xtra.co.nz>
Source record: 92719
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.misc,rec.radio.shortwave

Hi,
Does anyone remember a weird compact antenna that was featured in a 60's (or early 70's) edition of "73" magazine. Had 2 etched PCBs (like spaced plates) mounted inside a plastic bucket, and fed with coax?
Does anyone know more details of this?
JEFF

Shakespeare makes exactly what you want, but you can't afford it. It is
self supporting up to 15 knot wind, the nylon guys are necessary above that.
Shakespeare calls it a "Style 120-60", Military nomenclature is AT1011/U.

150. 2m 70cm dual band homebrew?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-04 23:30:08 UTC
From: chris@amos.yipyap.com
Message-ID: <slrnceh4o0.kr0.chris@amos.yipyap.com>
Source record: 92571

I just purchased a dualband vhf/uhf radio
but I don't have any dualband antennas.

I would like to know if there are any
on-line plans for dual band antennas
that I can build _without_ benefit
of a antenna analyzer or 70cm swr
bridge. This would be for mounting
at home, not mobile or portable.
And I prefer something omnidirectional.

I have some aluminum stock lying around.
Any ideas?

My homebrew 2-meter j-pole (made from 450-ohm ladderline) is also
resonant on its 3rd harmonic, 70cm, and has reasonably low swr on both
bands.

Just do a net search for 2-meter j-poles. Easy to make. And you'll
have a dual bander.

Howdy radio aficionados,

On this July 4th we are pleased to reveal the packaging and engineering prototype of Computeradio "Dream Radio One". It features stainless steel cabinet which will fit in the carry-on luggage, color LCD display, ergonomically designed controls (large tuning knob, key/paddles, foot switches yet to come) with two top notch ham band receivers, transmitter, spectrum analyzer/recorder with general coverage receiver in modular packaging with user programmable software.
You can peek at the picture of the system at http://www.computeradio.us/

Happy Independence Day and let the Freedom Ring!

Yuri, K3BU.us

Third harmonic UHF verticals are not a good idea. The take-off-angle
is about 47 degrees so most of the RF is lost. Yes, they work after
a fashion, but not nearly as well as a 1/4WL vertical.

You can buy mast sections on E BAY made of either aluminum or fibre glass
(which can interconnect) upon which you can stick on aluminum(sticky back)
tape. They come in about 50 " lengths and slide into each other. You can
also buy a tripod connection into which you can place fibre glass sections.
Diameter of mast is about 2" From memory a 50 foot pole was less than $50.
You could also add telescopic Roach (crappie) fishing poles which are 20'-0"
long which are also on E Bay at about $30 for two. There are lots of
inexpensive ways to make antennas for field day and hikers.
Have fun
Art

Was it in the April issue? A lot of "fools" fell for such articles in
73 Magazine, Hi.
One such antenna was to be buried under ground then the "polarity" of
the radiated
wave would be "inverted". ;-)

There are a few who experiment with "EH" antennas, where a coil is
placed in coffee cans,
spaced at different intervals for the band the antenna is to be used.

Congratulations, Yuri! Your DR1 looks great! It;s been evident from the expertise displayed in your posts that you are a very knowledgeable guy, but this revelation is icing on the cake--talk about surprise!.

I noticed that you moved from Canada to New Jersey in 1986. I lived in central Jersey, in Dayton near Princeton, for 31 years while with RCA, but I hadn't heard of Pine Brook. Is it near Edison? I have been in Edison many times, including visiting the Edison Museum during the 1950's.

I wish you the best with your new project, Yuri,

Walt, W 2DU

I recall one in a publication (S9) aimed at CB'ers back in the 60's. It used
printed circuit boards as you mentioned but also incorporated a nice husky
resistor that turned the critter into a dummy load. The article didn't fess
up that it was an April fool joke until the next issue. Wonder how many fell
for it? RM~

I'll second that. I built a copy of the Arrow antenna from the Arrow
plans and it has low SWR on both bands and works okay too.

Not too expensive to buy either if you have more money than time.

Ok, I'll fess up; I had the eagles but mine refused to ping after I built a Wayne Green circuit (I think he nick named it the "Mule Box") which was a clamp tube circuit that ran the Brownies double sideband reduced carrier. It drove the locals nuts watching their s meters going nuts. I wasn't much into gab but enjoyed tinkering with the equipment more than gabbing on them so soon sold out except for a CB I used in the truck. I drove an 18 for a living and retired in 84 and haven't keyed anything since. RM~

huh?
who works for free?
and what does this have to do with finding a good condition used ringo 10
meter antenna?

I just don't have $105.28 (total cost after s&h are added) to get a new
one). if I can find one for $50.00 or less, I'd be happy with it.

Hi Walt,
Thanks for kind words, coming especially from you. I enjoyed your Dayton presentation and been learning from the balun/matching wars here on the NG (I am trying to avoid them, keeping systems 50 ohms all the way :-)

I figured timing is right from my personal side and where the technology is and going. Ambitious project, but I always was intrigued by "impossible" tasks, have tackled few in my professional career, so I hope that this one will be "just another one."

Actually, I am debating if antenna tuner should be included, or in higher class of radio one should expect amplifier or tuned antennas to follow. It can always be an option, they are getting small (our expected output is 100W) and should fit inside.

The DR1 is my present to America and hams on 4th of July in thanks for accepting this BUm in search of freedom.

Pine Brook is in Montville township, area where Morse and Vail pioneered the telegraph stuff, next to Boonton (Instruments ex home), by intersections of Hwy 80 & 287, about 8 miles north of Morristown. There is still some of that spirit floating around here.

God Bless America!
73 and thanks again!

Hi Gang

Last night was the 4th (doh, we all knew that!)

But how many of you woke up this morning with a rocket perched upside down on top of your tallest antenna?

I have a Diamond triband 2/220/440 antenna up some 60+ feet.
The remains of a finned rocket about 10 to 12 inches tall has managed to land on top of this antenna, nose down fins up. Right now it's at the very top, but I'm sure in a few days will probably slide down the antenna shaft coming into contact with the radials.

Should I worry about this (chemical reactions) or just forget it and let time and weather take it's toll on the remains?

Hey Yuri:

Congratulations. Great start.

Outside of stainless steel looks great, and as we all know there's nothing like cold rolled steel for good emc control, ruggedization (smacks of MIL STD 810)and the steel could also be used for conduction cooling the PA to eliminate fan and fan noise.

Overall I believe the "dream package" needs a little "miniaturization".

Big flat color LCD screen is fine, big fat tuning knobs are great too, especially good for us old timers with dimming eyes and waning fine motor control. By now most have mastered the keyboard so I approve...

But... radio/cpu chassis could be smaller, with today's technology y'all should be able to fit everything but the power amp inside the keyboard.

Now that you've got the outside done, it's on to the tough part... the insides!

Most, but not all, of the innards can/should be "integrated" these days.

Plunk down a MIPS 64 core or two, run em with real time Open Source Linux to keep expense down, throw in a couple of SHARC DSP's, 24 bit ADC/DAs, and a couple of those big Xilinx FPGA's and there's nothing between you and success but software!

;-)

Good luck, I wish I had the time to help ya'll with the Dream, but I'm too busy now getting baby into the air...

Best wishes on The Fourth from another who has also adopted the USA as his own. Thank you USA for all the sacrifices you have made over the years to keep the world free!

Hi OM,

More efficient that what, a resistor? 75% less energy than what, a
resistor?

The eh antenna is one of several of a class that take more effort for
less return than simply putting up as much wire as you have room for -
even if it is the same size as any of these "amazing!" antennas.

The absurd claims that attend the cfa/eh/fractal crowing societies is
matched by their inability to prove them except through their own
special math (never mind the S-Meter).

However, there are those who argue SWLers need poor antennas and I
suppose these fit the bill nicely. The technical equivalent of cell
phones VS string-and-dixie cups tho'.

At the risk of giving away secret(s) that will require The
Gunnison Valley ARC to bust their butts even harder next year
to remain in the Top Ten of the 1A class, here's the 40M
vertical I built for us. At 2 A.M. it yields DX-style pile ups.
(Of course, "DX-style" pileups can be a curse -- they lower the
Q-rate.) Several times we have achieved 40M-WAS during FD.

It's a 2-element phased vertical made of ten-foot sections
of top-rail fence pipe. Each vertical, of course consists
of 3 sections to get to 30'. Then, a Big Hair Pin made from
10 ga. aluminium wire is pop-rivited to each top section to
Go The Extra Distance.

As best I can do in ASCII art, here's an astronaut's view of
the sucker:

```
. .
\ /
\ /
\ /
\ /
*-------------*
/ \
/ \
/ \
/ \
```

Of course, if you're not using a fixed-pitch font on usenet, then
this is a lot of gibberish....

All the guy wires are attached at the 20+ foot level --
just above the 2nd junction (i.e., at the *bottom* of the top
section). The center guy simply runs vertical-to-vertical.
In other words, there are only 4 ground attached guys.
It can be erected by three fellers in calm air (not recommended.)
Four fellers can throw it up easily.

You want to seek out the top rail fence pipe that has *DEEP*
slip fit joints. Ours are about 7".

I've already given away too much. HI!HI!
The phasing harness, the 1/4 wave matching section, the radials, and
controlling the directivity are left as An Exercise For The Student.

Thanks for comments Peter. Geez, I tried to minimize the package, but this is about the smallest I could come up with, there is just enough space inside for the air to flow. It is a complete station, 2 (or more) ham band RXes, 1 (or more) TXes, GC RX, spectrum analyzer, display/recorder, 100 W PA with super filters, 6 antenna switching and RX protection, PS, antenna/rotor controls, rear panel PS exhaust and all the connectors plus, while keeping 6 PCI slots for max flexibility (VHF/UHF converters). DR1 replaces just about full desktop of existing boxes (FM and TV tuners incl.) and less than half the weight of regular TRX. Also trying to accomodate present and future variety of hardware, preserving modularity. All you need is to add the amplifier (carry-on PA1 coming after DR1) and hook your antennas.

The pocket version will be the next project :-)

The picture is a good idea, but please post it so we don't have to
wait for when/if it gets published! I wouldn't worry much about
chemical reaction, the propellant was probably expended though there
are likely trace amounts inside the tube (from the charge that pops
the parachute) and if the burned out engine is still inside the rocket
I doubt it will slide further down your antenna. It will take a while
for the weather to take care of this, so if it is affecting the
antenna's performance you've gotta make the climb ..... but not
before getting a good picture of it!

73 & good luck,
Howard

Hi Yuri,

I don't know what happened. I composed a long response msg to you, and as I was getting ready to send it the screen flipped to the next post below, the one from Peter. I'm using Agen, and it's not very user friendly. I've searched Agent as far as I can, but the msg is gone.

Trying to recap some of the original msg, I said I made a Dayton presentation in either 1983 or 84. My only time at Dayton since then was in 2001 to kick off the debut of Reflections 2, but I made no presentation then. Were you there in either 1983 or 84, or could you have mistaken me for someone else at a later time?

I lived in Dayton, NJ from 1949 to 1980, when I retired to DeLand, Florida. When ragchewing on the air people asked where Dayton is. So I told them I live about 800 mi east of Hamvention Town.

I now live 6 mo in DeLand and 6 mo in my home town of Mt. Pleasant Michigan, where I am now, a city of about 26,000 pop. There are more than a hundred hams here now, but from 1933 (when I first became licensed) until 1939, I was the only ham in the entire county.

I was telling you about two other items in the msg that got lost, but I can't remember what the were--par for the course at 85, but pretty good that I recalled the three items above, eh?

CUL, Walt

Well, since the topic is shifting, can anyone tell me what the echo is supposed to do? in my travels, with my CB on, I can "hear" people with echo mic's and I'll be darned if I can hear them well at all. Now echo AND way overmodulated, now there's the ticket to complete unintelligibility! (is that a word?)

They "think" it makes them sound better or more cool, not sure which.
Problem is, most are turned up TOO far. Some isn't so objectionable and
doesn't sound bad, even though they're not supposed to be permitted per part
95. I've heard so many that sounded like they were talking either
underwater or with a mouth full of something. REALLY SUCKED.

Being both a ham and Cber, I can't see what their sense of existence is.
Then too, you got everyone and his brother cranking up the RF out, and if
they go channel hopping, that bleeds like hell. I had to take a double take
one time when I and a friend of mine were in another CB shop, and actually

heard two CBers swear off the extra garbage and go back to stock TO HEAR! WOW. I asked my friend if I heard right, and he agreed. I don't do any mods to CBs or other radios unless permitted by law or needed to get the thing working, when a unit comes to my shop. Many don't like my approach, but so be it.

Lou

RE: Audio enhancement

All modern ham rigs incorporate compression in the audio chain; this effective pushes up the room sound a bit without the echo/reverb being overpowering.

It is puzzling why hams have not commonly adapted well-known psychoacoustic observables to increase intelligibility. These include: a 50 ms delay on transmit; and binaural (delay and phase invert) synthesis on received. The latter has had some exposure in recent years.

I recall using both the of these circa 1985 at Field Day with pro audio outboard boxes. The problem--on transmit--is isolating them from the RF so they don't overload.

CB has always had an over the top approach to audio--which rather defeats the purpose of said synthesis.

Anyway, old stuff, well-known to music producers and some audio engineers.

73,
Chip N1IR

Check the Recycle bin?

I was almost every year in Dayton untill we moved from Toronto to NJ in 86. I am still uncomfortable with Smith chart, I rather design the antennas to be 50 ohms to 50 ohm cable and when monoband, I prefer to use Bazooka balun/filter. I prefer moving waves rather than them standing :-)

Congrats on your 85 and going, just stay away from carbohydrates and have a drink with meal.

We are about 40 min drive from Manhattan and I go there few times a week to "enjoy" the traffic and parking tickets.

73 and thanks again!

RC,

Instead of playing the 'game' of posting a reply to anything I post.

Why don't you be helpful to the original poster and attempt
to answer his question.

First - What type (name) antenna is he talking about ?

Second - What is your 'expert' opinion about this antenna ?

Third - What are the technical aspects of this antenna ?

- - - - - The Original Question - - - - -

Hi,

Does anyone remember a weird compact antenna that was featured
in a 60's (or early 70's) edition of "73" magazine. Had 2 etched
PCBs (like spaced plates) mounted inside a plastic bucket, and
fed with coax?

Does anyone know more details of this?

JEFF
ZL3TNV

- -

It's much nicer and rewarding to be honestly helpful
. . . then simply hateful.

Like you? ;-)

Instead of playing twenty questions:
>First - What type (name) antenna is he talking about ?
>Second - What is your 'expert' opinion about this antenna ?
>Third - What are the technical aspects of this antenna ?
Let's all note that it was your introduction of 6 off-topic links to
an antenna who I have already responded to against these same three
preceding questions.

Hi OM,

The eh and their ilk are on every sucker list on the web. It is a
simple matter to NOT cross post your responses if they don't shine
under examination. It is also a simply matter to either stay
on-topic, or to at least follow your own side-thread.

Respond to the technical issue, or learn to unlink your posts.

Steve,
If the salt water isn't used as 'part' of the antenna system (ground for a vertical, perhaps?), it isn't going to make a lot of difference, one way or the other. Are the palm trees far enough apart, and are there enough of them to put up a dipole?

Story snipped.

What are the odds? 'bout the same as this:

About a year ago (7-8-2003) the XYL and I loaded up the fifth-wheel trailer and hit the road. I don't operate mobile but I did pack the TS-870 and some coax and wire.

One of our first stops after leaving Tucson was to visit an old friend and fellow Hughes retiree, Darv, W7KNA, in Eagar, AZ. We spent a night (7-9-2003) at his place and headed then headed east. We didn't set any schedules or even talk about trying to keep in touch. Darv usually works 40 meters.

On August 26 we were camped in Governor Dodge SP in Wisconsin. Finally there were some trees and we were staying for a week or so visiting the parents of my next door neighbor so I pulled a 20 meter dipole up into the trees. I tuned 20 meters for a bit and not hearing much I decided to call CQ on 14.195.

You guessed it. On the first call I was answered by W7KNA.

Again. No schedule or plans to look for each other. Two guys randomly on the same frequency at the same time with propagation to each other.

hello, I am looking for a 2 Meter 4 element beam design, preferably for a 4 foot boom, because I have an 2M antenna right now, but it's not configured for 144.200 like I want to use if for, the elements are too short, and I wanted to basically know if the spacing is correct for 144.200 or would I have to change that along with the element length. the frequency of the antenna now is approx. 165.00. Thank you very much.

Sounds more like a model rocket than a firework. If it is, the
materials may be more weatherproof.

In either case, it doesn't quite seem within normal legal usage near a
residential area.

As said, most likely any propellant is gone, and the main concern
would be physical damage from the wind moving it around.

Happy trails,

Limited Space HF 40 Meters Antenna

For The RV And Apartment Dweller.
On a budget, Mobile in an RV, or live in a space-restricted environment?

Here's a great solution: HF Horizontal Polarized Di-pole Antenna
that will take those beams strait on.
With the station operating with gain and power, typically beam
antennas transmitting in the horizontal polarization.
By combining a pair "two" of our single band HF Mobile Stick
Antennas with tunable-tip's, you can have an ideal, single element,
horizontal dipole.
You are then transmitting and receiving in horizontally with
polarization.
Then by adding an inexpensive TV Type Rotor, you in effect have
Simple Rotatable Beam Antenna.
This antenna opens the world of HF communications for the
apartment dweller, RV HAM, Field-day Operating, and a variety of other
uses and applications.
o Features: The Antennas Features (2)HF-Stick Antennas heavy
Duty Copper Wire wound On 3/8" Fiberglass with Chrome Plated Brass
fittings and 17-7 Stainless whip..
o Hardened Aircraft Aluminum Mount

Dustin,
As a Michigander (relocated to California 24 years ago from the Bay
City area) allow me to offer some assistance. If you want something
'on the cheap' the following site has just what you need - yagi's
built with wood & wire: http://www.clarc.org/Articles/uhf.htm

If you are willing to look at other options here's a Moxon rectangle
that will give 10.71 dBi and though designed for 146 it could scale to
144 with minimal difficulty: http://www.cebik.com/moxbld.html

Are you married to the idea of a 4' beam or are you willing to go
longer? A longer boom (and a few more elements) will improve your
range; if your'e willing here's another wood & wire antenna called a
Quagi that works nicely. I did an 8 element UHF version and made
contact over a distance of 126 miles using 5 watts - of course more
power made me more readable but the point is more boom = greater range
(as a general rule of thumb):
http://commfaculty.fullerton.edu/woverbeck/quagi.htm

On your existing yagi did you mean to say it's tuned for 145.00? If
so then just play with the feed to get a decent VSWR and change it to
horizontal polarization and you're ready to rock. I've used a
Cushcraft 4 element beam that was tuned for 146 and the VSWR at 144.2
was close to 3:1 and the polarization was wrong - it was taken down
and replaced with a nice M2 7 element. I do however still have the
instructions for the Cuschcraft and if you'd like to use them as a
guide to building something let me know and I'll scan them & send them
to you. The difference in tuning it is where you place the shorting
bars on the T-match and requires no change of element length or
spacing.

Hope this helps & let me know if you're interested in the Cushcraft
instructions.

73,
Howard KE6MAK

This is stretching a simplified theoretical case, way beyond the point where it ceases to apply.

I agree that the maximum *theoretical* gain - ignoring losses - is achieved when the element currents are as high as possible, and the feedpoint resistance is as low as possible. This also requires that the element spacing is as close as possible... which leads to the interesting conclusion that a compact beam should have more gain than a full-sized one!

In practice, of course, this doesn't happen. The reason is that losses can *never* be ignored in this particular problem. As the element currents rise and the feedpoint impedance drops, the I^2*R losses in the

elements and the matching losses to 50R rapidly overtake any theoretical increase in gain.

This means that high-gain beams with deliberately high element currents are only a theoretical curiosity. The underlying theory has a valid place in academic textbooks such as Kraus, but it isn't relevant to practical antenna engineering. (Even superconducting elements and matching circuits wouldn't make such antennas practical.)

Also, it isn't correct to apply generalizations about 2- and 3-element yagis to a long, multi-element yagi. In particular, the first 2 or 3 elements of a long yagi cannot be considered in isolation from all the other elements.

It is true that gain optimization in multi-element yagis tends to reduce the feedpoint impedance towards 15-20R, but this is a remote side-effect of all the other design parameters. A low feedpoint impedance certainly isn't a desirable design aim in itself, because it leads to significant matching losses and a reduction in the SWR bandwidth.

Numerous designers have found that when they are getting close to a gain-optimized design, it is usually possible to raise the feed impedance back towards 50R by inserting an additional first director with a very close spacing ahead of the driven element. (This technique may have been developed after you ceased to take a close interest in yagi design, Dave.)

The close-spaced first director is mostly an impedance-changing device, and it has relatively few side-effects on the overall gain and pattern. With a multi-element yagi, it is usually possible to take out most of these side-effects in the next round of optimization. The result is a yagi that can be fed directly from 50R coax (through a balun) which eliminates matching losses and greatly improves the SWR bandwidth. If the re-optimization is done well, any decrease in gain is almost undetectable in simulation, and completely undetectable on the air.

I went through the calibration of my 949 recently by borrowing a buddy's Bird wattmeter and connecting it
in-line with my 949. The adjustment pots are easy enough to figure out from the silk screening and schematic.
I also used an external dummy load as the 949's resistor was outside the 5% tolerance. Easy enough to do with
good results and the only differnce between our units is a roller inductor.

Hi Wes

I LOVE hearing of rare incidents like that!

I was talking with an OM one night about 10 years ago, he was out in the Denver area, I don't remember off hand which band we were on, but in the background he had a 2 meter rig tuned to his local repeater. It was quiet, no traffic while I was talking with him at all. Then suddenly, as plain as day we heard a voice on the repeater come in about mid sentence of a Triple A towtruck driver talking to a stranded motorist, as the driver read back the license plate for verification, it was this fellows own car tags, so we paused our conversation so he could listen to the call, which must have been intermod of some type.

He was gone for a short while, but when he came back to the radio, he said, darnest thing, my car is in the garage! It was bugging him to no end, so he paused again to call Triple A. I hung around for about a half hour waiting for him and was just ready to call it quits when he gave me a call. That tags were from an adjoining state, but the irony of the whole thing was, both registered owners had near identical names. Not spelled the same, but close enough that they could be mistaken for each other when spoken orally. Dow Einsteen and Bo Weinstein or something close to those combinations.

I bumped into him on the same band about 3 months later and he was still talking about it!

If you can get 60 feet of horizontal space in the palms, consider running a random length dipole, fed with ladder line, and use a tuner. You can either just run 60 feet, or might want to let some extra wire hang down at the ends to make it longer. I'd probably do the latter.

If you are afraid of ladder line, there are trapped dipoles that will serve the purpose.

It will be pretty hard to define a "best" multi band dipole. But I really do like the ladder line/tuner combination. And with auto tuners like the MFJ, which will tune ladder line pretty nicely, they are the way to go in my book

p.s. I use a manual tuner for mine, and even those aren't too bad. I even contest with it.

RC,

The prior post to mine in this thread was a reference to the EH Antenna.

Yes I have an 'ego' and apparently your have an "EGO" too.

Hey, I try to be helpful and keep things positive.

I did not play Twenty Questions : I posted three.

I then provided Eight Links to more EH Antenna Information.
[Not Six Links.]

I also posted Eight Links related to the prior poster's
Screen Name: "JohnJacobJingleHimerSchmidt" {JJJHS}
[It's called relating to people / a side-bar.]

You have the tendency to state you opinions as facts; and
thereby discount all other opinions.

For some the EH Antenna may be a matter of 'faith' and to the
extent that it "Works" in some form or fashion: Hey It WORKS !
Your technical details valid or not, have very little relevance
to them and 'their' EH Antenna.

So Say I - My Opinions Stated as Facts ~ RHF

Hmm, a matter of degree not substance. As for substance I note you have no interest in engaging the outcome of your questions' answers nor in pursuing the technical claims of your submitted eh antennas. So I will respond to your style and expose your weakness in that regard too. ;-)

>For some the EH Antenna may be a matter of 'faith' and to the

Rabbit ears for AM reception WORK for the faithful too. Such a recommendation! It's like short-changing the blind to teach them self sufficiency.

>So Say I - My Opinions Stated as Facts ~ RHF

Actually "so write you." No one can hear you scream on the internet.

For others following the poor quality of discussion surrounding the eh antenna; this design has been field tested, studied and analyzed quite thoroughly on rec.radio.amateur.antenna. It is quite an education to simply look at the field data offered by the proponents themselves (who are just as incapable in reading engineering reports as any Yahoo).

For the sheer bulk and complexity of the eh design, their own reports shows it to be fully 0.1% to 1% efficient compared to a simple design. Of course, few of you may be capable of erecting this simple design. However, going to the trouble with the eh when you could as easily use rabbit ears purchased at Radio Shack must bring with it what Yahoo cites as the misty-eyed boon of faith (which accounts for easily 20 over S9 signals in an S1 field of noise where the faithless only hear static).

Henceforth we can call these designs Faith-Gain Antennas. It means that if you discard tuners, preselectors, tuned antennas, and simply use a wire coat hanger; that if you squeeze your eyes hard enough and fall to your knees with folded hands held slightly above brow level, then you too can enjoy the melodious tongues from other lands communicating to your inner heart - don't forget to turn on the radio.

Hi Bill,

AM. You've never tried it when your car antenna works every time? I
bet you have rabbit ears embedded in your windshield.

O Ye of little Faith!

Yahoo's very limited experience will probably miss this simple
observation of an antenna that WORKS. He would also probably miss the
common sense suggestion that AM DXers use automobile radios for their
listening - on long antennas.

For small quatities that would be the simplest. Where McMaster really
shines is for getting really odd types of material.

I'm surprised that the local Home Depot or Lowe's or other home center
didn't have it, even though PVC and CPVC have taken over most of the
market for plumbing.

Tough to get the plastic pipe to conduct RF, though.

Happy trails,

221. Re: How to Measure a 2M Yagi Impedance?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-07 03:13:48 UTC
From: Tom Ring <news0000@taring.org>
Message-ID: <40eb6a6c$0$5856$39cecf19@news.twtelecom.net>
Source record: 92492

As a sidebar, we found while testing 432 beams at Central States, that our older beams, only a couple years, seemed low in gain. We ScothBrighted the elements, Al welding rod, as I remember, with a hobby brass driven element and T match, and got 3 or 4 10th's more on a 17 foot beam I designed for EME than I had on the 1st range test.

Sorry about the looong sentence.

Well mine was as follows.....

In the early 1980s I was working as a salesman in a marine instrumentation manufacturer in South UK and much of our product went to Aberdeen in Scotland about 500 miles North of us, in the oil exploration days in the North Sea. I spoke to about 50 people up there regularly (sales) and "knew them" quite well / recognised their voices......

One day I was dialling "X" and got a crossed line - I listened for a few seconds and then couldn't believe my ears... - it was "Y" talking to "Z", both of whom I knew, and both of whom were discussing buying something from me (my company) each was in a different company up there about 5 miles apart.... I broke in and they could hear me too and for a short while we were all aghast at how tiny those odds must have been.

I rarely get a cross line let alone with anyone I know, let alone with two people I know, and let alone talking about me !!! It will never happen again..... There's something slightly spooky about that..

Nick

223. US Mail order ham outlets ?

Newsgroup: rec.radio.amateur.antenna

Ham Radio Outlet (HRO) http://www.hamradio.com/

Amateur Electronic Supply (AES) http://www.aesham.com/

Texas Towers http://www.texastowers.com/

I am sure there are others, but these three are about the biggest.

My personal experience is only with HRO, as they have a shop about an
hour's drive from here.

Having it sent to a US address, and then sent to you, might simplify
things a bit. The first two above will do international orders, TT
will not.

Hi, Nick,

Gary is absolutely right, let the stuff been sent to your relatives, whatever it is, it is much cheaper over there. BTW try www.gigaparts.com they have good prices, and they also ship to EU. Then take a week or two off your work and fly to your relatives to pick it up. The price difference will pay for your travel.

To avoid customs troubles (not about the customs tax, HAM gear is not taxable or taxfree) but the CE certification, which the US-rigs dont have, It is much easier to import the gear by yourself, so you can stet this is used amateur radio gear, maybe you put a sticker with your callsign on it.

Two OM I am friend with did both things. One ordered a TS2000 from Gigaparts, delivered within two weeks to Austria, then four weeks of hassles with the customs about the CE sticker. It took him quite a bit of effort to put in to convince the customs of the identicality of the US and EU radios.

The other one flew to Hamvention at Dayton this year, bought a TS480 for less than half the price of Austria, had a great time and imported the "used" radio with no problems.

Hope that helps for you also, Nick.

OK.

1969, Osan AFB, ROK.

I'm an Army E-5 and go into badge and ID to get a new ID card and plop my papers on the counter.

Guy behind the counter gives me and my papers the triple take, gets a set of papers of a desk, plops them on the counter and says "This guy left 10 minutes ago, what's going on here".

I see a picture of what seems to be me as an Air Force lieutenant.

Same height, weight, color of hair and eyes, same mustache, same first and last name, facial features close enough to pass. The only difference was our middle initials and Air Force instead of Army.

It took a while to get my ID card...

Check their store locations on the web. Maybe there is one in a city you are
visiting. Unfortunately, NY is not one of them.

May indeed - but then you really don't know how well do you? We can
agree you are unsuited for this forum's agenda.

>> For others following the poor quality of discussion surrounding the eh
>> antenna; this design has been field tested, studied and analyzed quite
>> thoroughly on rec.radio.amateur.antenna.
>
>RC - They may wish to also seek an 'alternative' view point

We can both agree they "may" rather seek to go to Disneyland instead.
However this is not rec.radio.tourism nor rec.radio.therapy.
Netiquette demands you post appropriate responses.

>> It is quite an education to
>> simply look at the field data offered by the proponents themselves
>> (who are just as incapable in reading engineering reports as any
>> Yahoo).
>
>RC - Yes as you have 'noted' I am Yahoo.

Of that there has never been any doubt. We both agree you can't read
an engineering report. One can only wonder what point you have to
make beyond tepid repetition of mumbled Te Deums. If you are ignorant
of their own data, I see little purpose to your correspondence here.

>> For the sheer bulk and complexity of the eh design, their own reports
>> shows it to be fully 0.1% to 1% efficient compared to a simple design.
>> Of course, few of you may be capable of erecting this simple design.
>
>RC - For those who wish to seek an 'alternative' view point

We both agree that you have no experience with it yourself to contradict their own reports of its abysmal performance.

>RC - When all you have is a single short WHIP Antenna built into your
>'portable' AM/F/Shortwave Radio. A pair of "TV Rabbit Ears" properly
>connected to the radio; may indeed function better as an Antenna.

At lest we agree you still don't know how much better, and in fact you don't even know if it would be better, do you? You seem wholly disinterested in the discussion of the merit of antennas - shouldn't you take up a hobby that engages you more and participate in their groups?

>> Henceforth we can call these designs Faith-Gain Antennas.

>Faith-Gain Antennas - How They Work... God Only Knows ? ? ?

All can agree you don't.

Hi Jim,

I couldn't help but reflect tangentially on another ID card incident.
This time with the Navy and the head of the Nuclear Navy himself,
Admiral Hyman Rickover. He was a thorn in every side at every level
(but that is how to make an honestly robust and bullet-proof weapons
system unlike star wars).

To test security, he made an ID card with the picture of a monkey on
it and then wandered through secure areas. He was challenged along
the way, and you are to be sure those who simply saluted the uniform
were cashiered. Hymie cut a wide swath through a lot of bases a lot
of brass and congress. The only other figure in DC that was as feared
was J. Edgar Hoover.

Places that do mail order have an incentive to only have retail
locations in no-sales-tax states. If they have a retail location in a
state, they have to charge the sales tax for all mail orders to that
state. That will increase their sales.

For example, Mass has a 5% sales tax on most items. NH has none. Quite
a few companies have nothing in Mass, but retail outlets just over the
border.

Note that NY City has a 3% sales tax on top of the 5% NY State-wide
sales tax.

In addition to those mentioned by others:

Universal Radio www.rffun.com

R&L Electronics www.randl.com
(I have made one purchse from each of these and had no problems)

I have bought from HRO as well, both by telephone and over the counter
in NH and CO.

HRO has free shipping on most orders over $100. Many others will charge
shipping.

I'm chuckling <grin>.

Right off of US Route 3 at the NH/Mass state line there is a VERY VERY large shopping mall. One day, about 2 years ago, I was looking for a parking place at that mall and driving everywhere in the parking lot. I had my GPS receiver in the truck. I was totally amazed to find that most of the parking lot is in Mass and the southern most store is just [JUST] over the state line into NH [depending on GPS error about 10 feet into NH]. I judged that the building sidewalk is in Massachusetts and the outside wall is in NH.

BTW, I live in NH.

When I said "just over the border" I wasn't kidding. ;-)

The town I grew up in was "dry", not allowing any liquor sales. You
could easily identify the borders with the non-dry neighboring towns,
because of the liquor stores. One of them had half its parking in the
dry town, but the door and the cash register clearly in the other
town.

Aren't those arbitrary lines on the map lots of fun?

That's a cheap shot, but it's a cheap shot worth thinking about. Sometimes
the users's expectations and expertise - or lack thereof - are the deciding
factors
in whether something "works" or not. The EH antenna may work for some people
in the way that homeopathy, brightly colored sugar pills, and other quack
remedies work in medicine, but Richard is right, the technical qualities of
antennas
can't be revealed by testimonials or protestations of faith.

Hi Rich

I shouldn't probably say this publicly, but it was so many years ago
it probably wouldn't matter today anyhow.

A was working for company that worked under government contracts, we
all had ID badges of course.
Because of my and other co-workers clearance level, we had badges that
without close examination looked like the upper echelon of a
department we had to walk through a few times.
This caused all the workers in that department to begin working hog
wild until we had passed through.
But that's not the funniest part. Each of us in the team I was in had
black dot security clearance as well, which just appears to the eye as
a black dot on our badges.
A few of the upper echelon of the other department wanted to follow us
so they conveniently placed a simple black dot on their badges and
tailed in a secure area with us as part of the group.
No sooner than the doors behind us shut, the security doors in the
hallway slammed shut as well and we were all trapped like rats in a
maze until security came and hauled those not of our group away.
Every single one of them got the axe, even though they were part of
the upper echelon.
We too got into trouble as being the group that held the door open for
them to come in, which was a bummer. But our trouble was just a 2
hour long lecture (on the clock).
This was way back in the 60's and security monitoring equipment was
quite advanced back then. I hate to think of what it is today!

Hi Gary,

Unfortunately, the top team in power has lost ground in that regard. The following clip (very much like your story, sans the concern) is from "The American Conservative":

==========

In early winter, an incident occurred that was seared into my memory. A coworker and I were suddenly directed to go down to the Mall entrance to pick up some Israeli generals. Post-9/11 rules required one escort for every three visitors, and there were six or seven of them waiting. The Navy lieutenant commander and I hustled down. Before we could apologize for the delay, the leader of the pack surged ahead, his colleagues in close formation, leaving us to double-time behind the group as they sped to Undersecretary Feithï¿½s office on the fourth floor. Two thoughts crossed our minds: are we following close enough to get credit for escorting them, and do they really know where they are going? We did get credit, and they did know. Once in Feithï¿½s waiting room, the leader continued at speed to Feithï¿½s closed door. An alert secretary saw this coming and had leapt from her desk to block the door. "Mr. Feith has a visitor. It will only be a few more minutes." The leader craned his neck to look around the secretaryï¿½s head as he demanded, "Who is in there with him?"

This minor crisis of curiosity past, I noticed the security sign-in roster. Our habit, up until a few weeks before this incident, was not to sign in senior visitors like ambassadors. But about once a year, the security inspectors send out a warning letter that they were coming to inspect records. As a result, sign-in rosters were laid out, visible and used. I knew this because in the previous two weeks I watched this explanation being awkwardly presented to several North African ambassadors as they signed in for the first time and wondered why and why now. Given all this and seeing the sign-in roster, I asked the secretary, "Do you want these guys to sign in?" She raised her hands, both palms toward me, and waved frantically as she shook her head. "No, no, no, it is not necessary, not at all." Her body language told me I had committed a faux pas for even asking the question.

=========

This is of course entirely consistent with a DoD that sold the contract to build super secret Nuclear Sub propellers to a foreign outfit that immediately turned the design over to the Chinese. We have also commissioned the work for Immigration security to an offshore company completely acing out two American companies with a long track record in this business.

From: Albert <pass@pass.com>
Message-ID: <naroe09keqg40lrppgk4vdbbl2jh3opa6i@4ax.com>
Source record: 92519

I'd like to put up a 40 to 60 wavelength (per leg) vee beam for 144 Mhz. It would be 12 feet off the ground and unterminated. My hope is that the angle between the wires can be smaller than normal becasue the legs are relatively long.

How much gain (dbd) should I expect and about what take off angle will I have?

It will be for transmitting only. With the transmitter located at the feedpoint, is there any need for exotic feed methods?

What type of matching do I need to feed it with a 50 ohm output solid state power amp?

Thanks,

Art

249. Delta Sloper Question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-07 22:23:47 UTC
From: Tainted <scamp@org.org>
Message-ID: <totoe0h42qbfuupgactpnu44rg81ptpila@4ax.com>
Source record: 92520

Anyone know how many ohms I should be measuring at the end of a 25ft coax cable connected to a 60ft Delta antenna? Right at the 529 connection at the connection end of the antenna the resistance is infinite. But at the bottom of 25ft of coax feeder the resistance is about 5meg ohms. Does that sound right? Also, if I measure the coax at the antenna (not connected to the antenna (just going 25ft to radio) it measures infinite. Don't understand it. Does it have anything to do with my ground maybe?

Hi Art,

Too many details lacking. 40 to 60 covers too much turf (beyond the pun), you neglect how wide it will be at the ends too. I ran a couple of tests to see the gain from 17 to 22dBi and the Z anywhere from 200 Ohms to 2000 Ohms. One thing to consider is the "law of diminishing returns." The gain for a much smaller V is not much different from the giant one (think 3dB for each doubling - as a shorthand, I am sure this fails long before the 20, much less 50th, wavelength is reached).

I read a couple pdf's on the things where a couple hams tested 20 meter backpacker against a dipole.

When the test signals were coupled with a very short length of coax to the antenna, the EH didn't perform well at all. When coupled with a 1 wave length of coax, the feedline radiated, but not very efficiently, around 1% as efficiently as the dipole, IIRC. Forgive the numerical blunders, it was late, and I might have slipped a number or two! 8^)

A long coax version fared better against a vertical in a second test, but in all fairness, the vertical had a pretty lousy ground.

But okay, the thing worked. The authors concluded that what they had was a tuned circuit on the end of some coax, and the coax radiated more so than the antenna. This sounds almost like aa halfwave antenna with it's tuned circuit. Any relation there?

All in all, it sure seems like a lot of trouble for a so-so antenna, and since I don't particularly like RF burns and radiating coax, I think I'll pass! 8^)

Near zero. As I understand a Delta, or Delta Loop antenna, the DC resistance should be zero ohms. The Delta is a closed loop. Down at the end of your coax the DC resistance will be zero from center conductor to shield. Probably need to disconnect the the coax from the antenna and check them seperately to insure the coax is not shorted, and the antenna reads a short.

>Right at the 529 connection at the connection end of the antenna the
resistance is infinite.
Not sure about a 529 connection, but if you take the ohm readings with the antenna disconnected from the coax, you should find the problem.

OK, thanks Richard.

How about this.

30 wavelengths per side, average conducting ground, 12 feet above ground.

What angle do I need for best forward gain, what will the takeoff angle be at that angle?

If I can get the entire antenna up to 20 feet above ground, how much better is the performance?

Is there any way for me to do modelling myself without burdening you or someone with a modeling program? I am not aware of free software that will model rhombics or vee's.

Thanks,

Art

ky1k at pivot dot net

PS: Some additional info. This is for EME, which does not require much movement. Since it is so long, it won't be variable in the elevation angle anyway. But, I hope to move one wire a bit so I can steer the beam to the left or to the right a little (changing the angle of the vee at the same time).

The problem with the EH and CFA as has been pointed out many times is the claim to provide Electromagnetic radiation through Poynting Vector Synthesis. They produce the E and H field seperately and combine the two in the antenna to produce EM radiation. The claim is with this Synthesis, high radiation efficiency is produced from a very small antenna, the Holy Grail, a small efficient antenna.
If someone gets results from one of these antennas, it is due to feedline radiation, so they will proclaim "it works". But it does not work because of Poynting Vector Synthesis as claimed. There are a number of ways to get your feedline to radiate, the EH antenna could be one of the better ones, along with the commercial Bilal Isotron.

>angle be at that angle?

The angles were pretty consistant at 5 degrees at 12 feet up. Gain
did not vary much either (5dB is a lot perhaps, but then there are so
many variables to consider).

>If I can get the entire antenna up to 20 feet above ground, how much

Hi Art,

With monster size antennas and a desire for accuracy, this drives the
model towards a lot of segments ($$$). You could use the free version
of EZNEC but it will blow up.

EME hmmm? Major lobe is 5 degrees off the horizon and 5 degrees wide.
Isn't there a problem with an antenna looking at the moon so close to
the horizon (ground temperature)? Also, the moon will only fill that
box for, what, 15 minutes?

You might find it simpler to build an array of dipoles such that they
were all looking up at the same box. Combining them may be a bitch
however, so I can see your desire for simplicity here.

Thanks to all for your help on this - especially to Crazy George who correctly suggested that the 2 directions are accomplished "typically a split phase AC motor, a common and one phase fed directly, the other through a phase shifting capacitor in the controller. Swap the two phase leads for reverse direction." This is exactly what this older rotor used.

Thanks to G.Beat I have excellent drawings of the rotor mods and clear schematics that I can use to build a revised controiller module. I'll post schematics when my experimentation is complete if others are interested.

Thanks again, Kevin VE9 XYZ

Art

Which brand of EME is this for? If for one of the new digital modes, you don't need that much gain, as you may already know. If it's for CW, having a ton of gain in one direction only gives you a very seldom available and very short window.

You would be better off sticking up about 15dBd of rotatable gain and making a horizon sched with W5UN. The 2m EME net is on 14.345 at 11AM central saturdays and sundays. Net control is VE7BQH. Dave, W5UN, is almost always on.

Dave also does the digi EME modes, and as a guess could probably work you on something like 10dBd with 100W on one of those.

I know Ian is an EME're, so pipe in, Ian!

Appreciate the help but it's not a closed loop. At least I don't
think so. There are two antenna lines - ones 60ft and the other 16ft.
They are connected to the 529 center post. The ground lead (30ft) is
connected to the outer part of the 529. I'm pretty sure it's right
that there is infinite ohms there because they are not physically
touching in any way. I'm confused because simply adding 25ft of coax
causes a 2.5meg ohm reading. In essence I'm still across the 529 just
25ft further away. So nothing should change.

Hi Richard -

Luckily, Rickover was never part of a weapons system. Or else, in addition to driving a submarine that was too heavy, too slow, and could not dive as deep as the enemy because of his assanine demands on the nuke plant, we would have also had torpedoes that were slower than the enemy that was hunting us. Bad enough that they dove deeper ran faster and had torpedoes faster than we were. I once had some twit Canadian who was visiting across Lake Erie when I was home on leave, tell me that the U.S. simply out-spent the Soviets in the Cold War.. That jerk-off would never know the harrowing times that we were nearly rammed by packs of faster boats that could sweep an area at nearly twice our top speed. They would race, stop listen, charge another direction, stop listen, etc. We out-trained and out-manuevered that dedicated adversary, and anybody that thinks differently reads too many novels..

Also, the Chinese never got our propellers, and it wouldn't matter if they did then or now. It was the Soviets that bought the ballbearing technology for sound silencing from Toshiba - who violated their contract by "sharing" it.

Best regards,

Jack

Hi Richard,

When I asked 'what angle do I need for best forward gain', I was
hoping you could give me an idea what the optimum distance between the
tips was.

My hope was that longer legs might allow me to use smaller angles
although I have a big field to play in.

Thanks,

A

Thanks for the eme advice.

But, I was asking about the gain of a vee beam because they are cheap
to build and easy to put back up when the weather takes them out. We
have major ice storms often here.

Which "Brand of eme' is irreleveant, gain is gain regardless of which
mode is used. Excess gain is never wasted, it either makes the QSO
faster or allows one to work smaller stations or allows SSB instead of
CW/digital modes.

If the angle of the V makes little difference to the actaul gain, it
can be steered by moving either leg, which is also easy to do.

Although I can only work on my moon rise or moon set, more gain is
always better. Since I can't elevate my yagi, a non elevatable vee
beam for transmit only might give higher gain. The yagi would be for
receive only.

Having different receive and transmit antennas has benefits as well,
such as no switching loss and no need to protect my gaasfet during
transmit.

Can you offer any suggestions regarding the original question?

Thanks

A

One time, a few years back, there was an elderly farmer living in
western Maine, near the New Hampshire border.

One day, a crew of surveyors from the state came by the area. They did
all of their sightings and measurements and calculations, and then one
of them went up to the farmhouse.

He asked the farmer how long he had lived there, and the farmer
replied, "80 years, next November, I've lived on this farm here in
Maine since I was born."

He told the farmer, "we've just checked, and the state border was
marked in the wrong place. Your farm is actually in New Hampshire."

The farmer said, " Good thing, too. Don't think I could have taken
another one of those Maine winters."

Happy trails,

Anyone know of a rotor repair service, other than Yaesu, for the G-800SDX rotor. Have a unit in need of repair and after much searching have come up with nothing. Checked all the old favorites, Norms, Rotor Doctor (CATS), etc., none mention the Yaesu line of rotors.

Any help would be greatly appreciated.

Hi Al,

Well, I don't do things by half, so I am building a matrix and decided to start with a 10 Wavelength V antenna located 5 Wavelengths above ground. In this case, the Wavelength corresponded to 2M (ï¿½) over typical ground using #14 wire from local hardware store. I varied the opening angle by increments of 10ï¿½ and observed that the feedpoint Z increased over most of this interval, and then declined. With an opening angle of 5ï¿½, it presented a near 1:1 match but with a gain at the lower end of the series: 9dBi @ 15ï¿½.

20ï¿½ opening angle offered both the best gain, 13.3 @10ï¿½, and a match to 90Ohms.

This pretty much represents the spread of gain values, the match values continued to increase in R to as high as 160 Ohms with gain varying between the two values already described at 10 or 15 degrees elevation. The highest gain azimuth was not always apparent against the V geometry. That is to say, it did not aim down the barrel.

Perhaps more reports later. However, as projects go, I am still working on the Lattin antenna others have described an interest in, and I have combined that with the Franklin antenna as part of a wide ranging survey of transmission line-like antenna designs.

(Still sleepy and jet-lagged...)

By coincidence, I was involved in just that kind of thing in 1979(?) when we made the very first 2m EME QSOs from G-land using amateur antennas at both ends of the path. One of our group was a farmer's son, so we were able to string a 600ft rhombic over a large field of pigs.

The quick answer about feeding a very long V-beam on 2m is to use a "universal stub" - a half-wave open-wire stub with a shorting bar, and a 4:1 coax balun. Adjust the tapping points for the shorting bar and balun to get a good impedance match, and away you go. The universal stub is almost a lost art, but any *old* VHF handbook will show you how to make one.

It's obviously much more convenient if you come down to ground level in high-grade open-wire feeder - not the store-bought stuff, but home-made, with close-spaced wires under tension and a minimum of insulators. You can then do the matching at ground level.

30 wavelengths per leg should be long enough to eliminate any termination requirements at the far end. Radiation "loss" from the forward-travelling wave will automatically ensure that the rear lobe is reduced. If you wish, you can terminate the far end of each leg with a 300R low-inductive resistor and two quarter-wave "radials" in a T configuration... but you'll probably not notice the difference.

However, it's true that:
>having a ton of gain in one direction only gives you a very seldom
>available and very short window.
>
This is a major inconvenience - you get maybe 20 minutes total operating time per day, on maybe 3-4 days per month maximum. And that's only if the direction of the beam is perfectly optimized. You need to lay out the antenna with an accuracy of about 1 degree maximum, so you'll need to borrow some serious surveying equipment. Guess-and-compass methods will not work, because even small azimuth errors could mean that you're operating on completely the wrong DAY!

(As the one who did the calculations, I can still remember the feeling of relief on verifying that the moon really did set in front of the rhombic, and on the right day too.)

Also, these moonrise or moonset windows will occur at arbitrary times of day or night. With absolutely no time to waste, you will be limited to making skeds... and not many sked partners may want to share that inconvenience with you.

Overall, I agree with Tom - a large fixed antenna was the right thing to do 20+ years ago, but 2m EME is now in a very different place.

A smaller steerable beam will trade raw gain for a huge increase in EME operating *time*, and with modern operating techniques, time is what you need the most.

Sam -

If you don't send it to Yaesu for service - it is up to you to repair.

Some web pages have information on minor repairs (e.g. ball bearing
replacement) --
BUT the limited availability of some parts (e.g. only from Far East if Yaesu
USA does not have part in stock) -
limits options. Norm's Rotor Service was recently purchased from original
owner (MD) and moved to Alabama.

I have just started to use my new MFJ 1876 located om my balcony.
Before the antenna went into operartion the motor unit has to be replaced.
:-(
However, my problem is that the antenna will not tune in the frequency area
10.1 - 18 MHz.
On higher band there is no problem.
I known that the loaction on my balcony is not ideal but i don�t think thats
the problem or?
Any ideas??
Best regards
OZ1JZV - John

Hi Ian,

Thanks for your comments.

My hope was to use a v beam instead of a rhombic.

The V is relatively easy to steer, especially if the performance doesn't change much if either leg is moved. Note that I hope to leave one leg of the beam fixed and steer the az by varying the position (and the V angle) of the other leg. Not sure how much changing the angle of the V impacts the performance, which is why I asked for someone with modeling software.

My hope was to exploit the high gain, simple construction (but poor receive) of the V for transmit only and to use the modest sized FO yagi for receive only.

If I can get 19 or 20 db from a big V beam, I can probably tollerate the limited operating time as well, Q's with big guns should take only minutes and medium sized stations should be workable in a 20 minute window.

If the computer model predicts a usable gain, I'd like to try putting one up.

Regards,

Art

|
|ky1k at pivot dot net
|
|PS: Some additional info. This is for EME, which does not require much
|movement. Since it is so long, it won't be variable in the elevation
|angle anyway. But, I hope to move one wire a bit so I can steer the
|beam to the left or to the right a little (changing the angle of the
|vee at the same time).

Since I worked VK5MC to complete my 2-meter WAC and he used a slightly
steerable rhombic, I'm not going to say that this won't work, but I
must question why. If you're going to limit yourself to a few minutes
of moon time a month, why not just put up a long fixed Yagi and use it
for both transmit and receive. A forty-foot long Yagi will give the

same gain as the vee, with a *huge* improvement in the pattern and it will have a much more tractable feedpoint impedance.

Wes

Hi Tam,

That would be an opening between 30ï¿½ and 40ï¿½ (106 to 122 Ohms) with a
gain around 12dBi (11.8 @10ï¿½ to 11.9 @20ï¿½).

Impedance appears to change smoothly through out the full range; gain
and angle less so (but no more than this spread of 10ï¿½).

Albert

I'm a little experienced with failure in trying EME on 2 meters. I'm not
a scientist, but have some information that might help you decide which
antenna is best for your situation.
I'm not able to calculate the amount of steering thats available with a
long V antenna. I couldn't even predict the antenna's radiation pattern
shape. If the antenna pattern has about equal beamwidth in both elevation
and azimuth, a 20 DB gain antenna will have about a 20 degree beamwidth (as
I remember).
You probably know all this, but--
The moon rises and sets at a slightly different azimuth each succeeding
day. The azimuth direction to the moon on the horizon might vary by about
50 degrees per year.
I consider the moon to be about 1/2 a degree wide. It will rise at "its
diameter" each 2 minutes.
It looks to me like you'd have a few minutes of 'max gain' each year, and
theres no way for you to predict _*when*_ because the "takeoff angle" at 2
lambda is unpredictable.
If my thinking about *where the moon is* is about right, I predict that
you wont be satisfied with an antenna that isnt more stearable than the V
for moon bounce.

I've read about a guy who made a long yagi antenna by suspending it on
ropes rather than 'booms'. I wonder if you might be more satisfied with a
yagi that you could "roll up" when icy weather approaches.

You might (as someone else suggested) be reading some leakage
resistance from your coax. 2.5 megs seems a low reading for coax in
good condition... if it's the coax, you might have gotten some water
or other contamination into the connectors, or into the coax itself.

Depending on how you're holding your meter probes when you do the
measurement, you might be reading your skin resistance by accident.
Make sure your skin isn't touching the metal parts of either probe.

Depending on the meter you are using, you might not be reading just
the resistance. Since you're doing a measurement on a coax and
antenna, the antenna is likely to be picking up some amount of RF from
nearby transmitters. There would probably be some differential-mode
RF within the coax (from in-band reception by the antenna), and likely
some common-mode coming down the outside of the coax. Your meter's
circuitry might be acting as a pathway to complete the RF circuit -
this would allow some amount of RF current to flow through the
metering circuitry (in addition to the DC current which results from
the resistance-measuring voltage the meter is presenting), and the
meter's reading might be the result of this small RF current flow.

As an experiment, try bypassing the bottom end of the coax... create
an RF short circuit across the PL-259 with a .1 uF capacitor. See if
this makes the apparent resistance at this point go up... if so, the
resistance reading was probably due to stray RF getting into the meter.

Hi:
Do you have the loop horizontal or vertical? Horizontal mounting requires it to be 20 feet (sorry can't do meter in my head) above ground. Your balcony most likely has steel structure holding it up and that is always ground. Try mounting it vertical if you have not already done so.

Hello i was wondering,
If i built a 4 element vhf lowband phased array antenna
With a gamma match.
and a phasing harness.

I was wondering , what would be the spacing from the mast to the element?
would it be? 1/4 1/2 or 1/8 wavelenth?
and what would be the formula for finding this distance?
this antenna wont be the folded dipole type.
it will have elements made from 3/8 aluminum tubing.
my second question is,
what would be the length of my gamma match be for a half wave element say,
on 50.000 mhz
and what would the formula be for finding this out.
i know the spacing between elements would be 1/4 wavelength. And the
elements would be a 1/2 wavelength. and the phasing harness is made out of
odd 1/4 wavelengths . but was never told the spacing for the element from
the mast or the length of the gamma match.
can anyone help/provide a website for this info thanks ..
ve3 tya

>
>Wes

Hi Wes,

Thanks for the information, it's just what I needed.

I am not sure how dbd converts to dbi, but a 100 foot 43 element rope yagi gives 19 dbd.

My motivation for starting this was that I had the room for a large V beam and that it might be practical if I could get the same gain as the big rope yagi.

The V beam is way easier to put up and much cheaper and simpler to construct.

From looking at data from smaller rhombics, it appears they are poor for receiving as they have some major lobes that point towards the high noise temperature Earth, which is why I wanted the V for transmit only. I don't think the radiation off the back of the antenna will do any harm in transmit only, so my hope was that it does not need to be terminated.

Your gain figures indicate this bears further investigation, even though I would be dependent on moon set or moon rise to make my Q's. But, people with yagis have had that limitation and live with it just fine.

I'll look up 4nec2 and try to play with it myself. Hopefully, it will handle large V's.

Regards,

A

Albert

I can't help on the V any more than others, such as Richard, are, but I can give you another cheap alternative that is as easy to repoint as your V, maybe easier. VE7BQH published a rope beam for EME a while ago. It is as cheap as rope and the elements plus TyWraps cost. The only downside I can see is making the match, but that's not really too tough, and you have to match to the V anyway. It will also have more gain than the V would for the same real estate.

Try Tim Davidson W3PLC:

http://www.tdcommunications.net/services1.htm

He did a nice repair job on my seriously scrambled FT-847 very
inexpensively while I sat there and watched. Nice shop, outstanding
individual. He doesn't specifically state in his list of services that
he fixes rotators but he mentioned that he does. You can't lose much
by asking him the question.

Hi Fellows.

I tried hooking a 2 mtr/440 MHz antenna to my Garmin GPS 90. Zip, nada!
I did this while doing a bunch of work on a passive filter to separate the
energy to direct it to the right place. With this result I discontinued the
project as futile.

I wish to dispel the myth that an antenna with a null overhead can not be
used as a GPS antenna. The satellite overhead does not stay in the very
narrow null long enough to be a operational problem. I used with good
effect a simple quarter wave vertical over a ground plane and my Garmin
locked up nicely. Translation: Stick a bent up paper clip into the BNC
jack as a vertical and the thing still works! Not as strong but no reason
to give up if your 'real' antenna gets busted.

For the ease of you folks who want to duplicate my experiment, my
math shows that the proper length should be 1 7/8 inches, or 47.6 mm
for the metric minded.

This is why you should only cross post for a really good reason.

The amateur newsgroups seem to have a plentiful supply of people that
are not knowledgeable about the radio hobby.

The example above is just the end of a thread of the BS that poses as
"knowledge" on the amateur news groups most days.

Hi

Thanks for you mail.

The loop is mounted vertically.

Yes, your are right. There is a lot of steel and aluminium in the structure
of my balcony.

I have tried to replace the loop but it still "refuse" to tune below 21 MHz.

I can se a small dip on the meter but are not able tuned it manually.

From 21 MHz and above I get a very low SWR.

In the instruction manual it is mentioned if there is a high SWR due to
placement of the loop, the feed loop in the antenna can be tuned to get a
lower SWR.

I have not tried this solution yet due to the good SWR on higher band, but
perhaps I should.

Hi John,

Yes, the manual suggests this, but it seems strange advice. Move your
antenna inside to a room that has less metal nearby (away from railing
and major building components) and confirm you "can" adjust for low
SWR at your problem frequencies.

I am planning a 20m vertical dipole array here (no room for a tower - yet) and am seeking some advice on the sizes of nesting aluminum tubing to ensure adequate strength. I've looked about in what I think are the usual web and non-web places and can't find any formal discussion. Anyone know of such a discussion or can perhaps lend some anecdotal info. Thanks very much in advance.

Since it normally requires more capacitance at that end of the band it was
my intent to make the capacitance larger. But it would appear that I am in
error and should be scolded , tho I hardly believe that it is inductance
should be added for it to present a purely resistive load, It will be
interesting to find out why.
Apologies for the incorrect suggestion

Unless what he wants to do is lower the frequency. It is, after all,
just a very leaky tank circuit with "no load". (That was "tongue in
cheek" for those of you that normally fail to recognize it)

Hi Tom,

But that is NOT what he is trying to do. He simply wants it to work
"as advertised." Everyone is re-inventing it to do what it was
already designed to do. It already resonates at these frequencies, to
add capacitance is very poor advice for any of several reasons.

What John needs is to determine if it is broke, or if it is
environment that is getting in the way. He is not asking for the
antenna to tune outside of its characteristic range.

The advice in the handbook suggests he open up the case and squash the
feed loop to compensate for nearby interfering, metallic structures.
This may solve the problem, but it is a piss-poor solution. If it
were a general, preferrable condition, they would sell them all this
way.

I would be amenable to seeing some specs rather than boxes.
Especially vs the Flex Radio- their specs and software are quite impressive.

Patience my dear Watson :-)
They are coming as we progress, we are aiming at beating what is out there and packing more stuff into a box. We are releasing info on stuff that we have, no vaporware or phoney specs and claims. Just want to alert to what is coming so you don't spend $10k on something that will not measure up.
Stay tuned!

I have a question please. I just purchased a IC2100H 2 meter.
Does any one have any Info(Good/Bad/Indeferent)about this radio.
Are there any mods that can be done to this radio?
Or do you know where Info may be obtained?

Thanks In Advance
Don

Well, how would you suggest he troubleshoot it?

I would drop some extra C in to determine if that's what's needed. What is it going to hurt? Otherwise all he has left, from what you have suggested, is to complain to the manufacturer.

At the least, he should determine what, if anything, makes a difference before complaining.

Hi Tom,

I've already addressed that, as has the manufacturer.

>I would drop some extra C in to determine if that's what's needed. What
>is it going to hurt? Otherwise all he has left, from what you have
>suggested, is to complain to the manufacturer.

Just "add some extra C?" Think he could find a 20KV rated cap with
100A leads at Radio Shack? Do you and Reg seriously think that a one
loop inductor and simple cap have been so confusing to manufacture
that gum and bailing wire will fix it?

We may as well offer him to file down the inductor to raise the R to
accomplish the same thing. It doesn't take much, a very thin saw
cutting a notch could do it pretty quickly. With luck, it may even
self-heal welding the slot shut.

The manual's suggestion to squeeze the feed loop is beginning to look
better already.

If it needs more C to tune, it isn't for lack of plates or their mesh.
More likely it is the capacitor drive system.
>
>At the least, he should determine what, if anything, makes a difference
>before complaining.

That has already been offered. If anything, John should determine
that it isn't a razor thin null that is escaping his attempts to lower
SWR.

Sorry, but you didn't address anything. All your previous responses follow.

Richard Clark wrote:

#1 -

It has a capacitor.

#2 -

Yes, the manual suggests this, but it seems strange advice. Move your antenna inside to a room that has less metal nearby (away from railing and major building components) and confirm you "can" adjust for low SWR at your problem frequencies.

#3 -

This is like charging the battery to fix a flat tire.

#4 -

ut that is NOT what he is trying to do. He simply wants it to work "as advertised." Everyone is re-inventing it to do what it was already designed to do. It already resonates at these frequencies, to add capacitance is very poor advice for any of several reasons.

What John needs is to determine if it is broke, or if it is environment that is getting in the way. He is not asking for the antenna to tune outside of its characteristic range.

The advice in the handbook suggests he open up the case and squash the feed loop to compensate for nearby interfering, metallic structures. This may solve the problem, but it is a piss-poor solution. If it were a general, preferrable condition, they would sell them all this way.

Sorry but none of this seems to be advice that would help him. You didn't address anything. All you seem to be able to do is criticize other's suggestions and offer nothing yourself.

I hope to actually see you try to help someone sometime.

At least I am trying.

I already have a 5 element, 6m beam installed on a telescoping pushup pole guyed with metalic guys. I'm thinking of putting a matching beam below the present one and phasing them (with top/bottom/both switching).

Will the metalic guys have much effect on the bottom antenna? There will be about 3 ft of clearance at minimum when turning.

I've got my 6 meter beam about the same distance from my guy wires and
haven't found any problems. Of course the guys were always there so I
don't have the benefit of a before and after comparison. I've checked
the VSWR with the antenna pointing different directions to see if it
changes as the position of the elements in relation to the guys had
any effect and there were no change. Once you've finsished installing
the second beam and the switching don't forget to point it toward
Southern California during band openings - I've got Illinois, Iowa and
Michigan but no Wisconsin .... yet, hopefully your new setup
will change that 8-}

73 & best of luck,
Howard

Have been on the Bay of "E", and found myself a wattmeter -"Sierra"
great instrument WITH SLUG (4 power settings, range from 2-30 MHz!)
, and bought for 75 bux with shipping! Was listed (in all places), on
the 2 METER page! , and less than 13 hours to be bought- no bids!
Yet, going to the Bird (oh , exulted one!) listings, see bids for
the following:
2-30 mHz slug, range -- 50 KW, bid on that is 36.99
2-30 mHz slug range -- 25 KW, bid on this is 60.00
2-30 mHz slug range -- 60 KW (hey, this aint even normal for the
meters)! Bid 31.00.
If this the new norm that is to bring technical compentance to amateur
radio, then I fear for it's existance!
And, there is a Struthers (similar to the Sierra) for bid, with 3 slugs
(each with 4 power levels, good to around 400 mHz), no BIDS (opens at
100 bux)! And the guy auctioning it, doesnt seem to know SQUAT about
what it even good for!
Beginning to think that Darwin had it BACKWARDS !! Regression of the
Species! Jim NN7K

>How much gain (dbd) should I expect and about what take off angle will
>I have?

Hi Al,

Contrary to Wes' results, I do not find much more than 13dBi, and certainly not from your proposed huge implementation running out towards 50 wavelengths. In fact, I find antennas that are a tenth of that (5M) have about as much gain as will be found.

My matrix of testing shows that doubling to 10 wavelengths and doubling again to 20 wavelengths brings no further gain (except for some opportunistic outliers).

As a variation upon a theme, I decided to play with uptilt on the 5 wavelength models, lifting the far ends by roughly 25 degrees. The feed point is at 3M, and the far ends are lifted 5M. With this configuration, there is some loss in gain, but the lobe looking at the horizon is easily four times broader. That is, there is an even gain of roughly 11dBi from 14 degrees above the horizon to 34 degrees above the horizon. This occurs for the tips being separated by 30 to 90 degrees (the gain falls to 9dBi with wider separation).

When you separate further, out at 150 degrees between the tips, the broad characteristic collapse, but recaptures gain, and puts it out lower. At such a configuration you might observe 11dBi @ 4 degrees. That lobe is only 3 or 4 degrees tall however.

Considering that common implementations of rhombics rarely go beyond a couple of wavelengths to several, it seems that 20 or 40 or 50 has no future. The law of diminish returns must occur somewhere as you are constantly losing power as it trucks down the length. At that far end, nothing added to little before it hardly piles up gain.

Those findings of "no further gain" and "no future" are very strange. In the real world, extreme-length rhombics on VHF do have high gain - and also a very distinguished past.

>The law of diminish returns must occur somewhere as you are
>constantly losing power as it trucks down the length.

All types of antenna suffer from diminishing returns, in terms of gain versus absolute size; and it is conceded that extreme-length V-beams and rhombics take up a huge amount of real estate for the gain they generate. But what you seem to be finding is a "gain saturation" effect that is more severe than the normal diminishing returns.

This is a puzzle: would you care to share some antenna files?

The supply and demand on ham related accessories is spotty. Typically takes 2 or 3 listings to find the right buyer(s). No point in essentially giving it away. Of course, listing it in the wrong place isn't any help--a common e-bay issue. Same issues with flea markets.

Keep in mind that the flea markets compete for the same buyers as e-bay, and e-bay presents some path to follow thru on a fair sale. Many folks, like myself, don't go, or almost never go, to fleas anymore. Antiquated in some ways.

Of course, there are few places like the hamster fleas, where you can get both donuts and chilli at 9 AM on a Sunday morning. Now there's an explosive combination for the non-Atkins crowd;-)

Hi Ian,

That currently runs to 62 files, some EZNEC+4 - give me something you
are familiar with.

I have EZNEC+ v4 too, but that is the only format I can presently read.
Please can you zip and send a selection of files that seem to illustrate
the point?

What Bill says is correct, and it is easy to implement on 6M. Put one
insulator as close to the mast as possible and another 4 - 5 feet down the
guy. Even though that is close to quarter wave, it isn't resonant unless
you leave out the insulator. That will put the unknown grounded remainder
of the guys almost a half wave away, which is barely acceptable, but better
than having them right up under the antenna.

Well, now you & Bill have me wondering if I should go up on the roof
and redo the guys ..... which is no easy task for me. I did however
use lengths that aren't resonant ..... aww heck, it's working now
so I guess I'll leave it alone until the next time I need to
add/change anything else.

Hi Malcolm

The 1/4 will easily cover the 500khz at that frequency.

I'd also suspect that even if you went to (say) a colinear antenna to keep the radition lower to the ground, there would be more than enough signal going "upwards" to the aircraft.I guess you cant actually measure signal strength of received aircraft? You may even find that (say) the lower angle of a 5/8 whip actually helps when the aircraft are some distance away...

I think the most important factor for comms with the winch site is to get both antennas as high as possible and if using a long coax run make it low loss. You have already indicated problems in this area. Possibly the winch install needs to be easy to knock down without damage?

Apologies for not being specific..

Cheers Bob VK2YQA

Source record: 92455

Hi,
I have an interesting problem which I'd like to put to the newsgroup for idea's. Our club (gliding by the way) uses just a few frequencies to transmit (AM) and receive on.

The main freq' is 129.975, but we go down to 129.900 and up to 130.400.

We need some new antenna's but I'm wondering what would be the best. Currently we use a quarter wave set for 129.975, but this is I'm afraid just cut to a length (the lads are pilot's and not Ham's !!)

The quarter wave of course is good in one respect that we are all hopefully up in the air so the high angle of radiation helps. It would be good though to improve the signal to our winch which is just 950 metres away (3100 feet for some!) but over the hill so to speak, so not line of sight. We struggle at times on our max 1 watt output to hear each other.

I'm wondering what I can build that will help this low angle but leave the high angle still there. Also it would help, to have the VSWR band width with us and not against us on all the frequencies. For the winch we have limited height available on the top due to hangerage restrictions. If I build something big and solid, some one is sure to forget and rip it off going into the MT hanger. Our base end is a good old English double decker bus, so we have a good ali ground plane some 20 feet in the air. None directional capabilities are of course required as we fly 360 degrees around the club.

Any thoughts out there?

Many thanks,

Malcolm - Radio Ham and Glider pilot.

Message-ID: <88516068.0407111723.7beb3699@posting.google.com>
Source record: 92459

Hi folks,

I have a bit of an issue with a new house i recently moved into and am looking for ideas on how to over come them. (I know running new cable and outlets would be the best solution, however the landlord would have kittens if I did that)

1> all antenna outlets won't work unless one particular point has a powered booster plugged into it.
2> this booster needs to be terminated to a device (ie. tv or vcr)
3> this outlet is behind a wall from where the tv is located.
on the other side of this wall is an outlet, however this is some 6 meters away from the tv.

So, I am looking for a self terminating plug I can put on the end of the powered booster and a device that can transmit the signal from the wall outlet across the room to the tv. At the moment I am running a massive length of cable from the booster to the tv (which I keep tripping over in the middle of the night).

cheers for your help
mark.

Hi All,

Following up with a series of 2 wavelength measurements, it is
interesting to note that of the series of 19 tests, fully 13 of them

evidenced HIGHER gain than those from the 20 wavelength series of measurements.

The step from 2 wavelength to 5 wavelength showed gains consistent with doubling the length of the antenna size for many separations (e.g. 3dB gain, or thereabout). However, it appears that beyond 5 wavelengths (considering my next cardinal point was a doubling to 10 wavelengths) no further gain was observed as a general characteristic.

If I were to judge this at the 180 degree spread and compare against ALL other designs; then the absolute greatest gain for a V design was observed to be slightly less than 4dB. In fact, the 2, 5, 10, and 20 wavelength designs configured as simple dipoles barely differed one from the other (1dB at most, and typically 9.9dBi).

343. ground plane for a magnetic mount cellular antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-12 08:40:41 UTC
From: hunwalla@yahoo.com
Message-ID: <ca70a89.0407120040.7319da2c@posting.google.com>
Source record: 92465
Cross-posted to: alt.cellular.tech,alt.cellular,rec.radio.amateur.antenna

Hi all,

My girlfriend's mother lives in an area with poor reception, especially indoors. I recently hung a little metal bracket from suction cups on her bedroom window, stuck one of those 3dB magnetic mount cell antenna's intended for a car roof on it, and ran the wire inside so that she could use the free long distance from home without facing the Florida summer heat. It helps quite a bit, but still cuts out.

I understand that when used as intended the antenna uses the roof or trunk of your car as a ground plane or counterpoise. (Are these the same thing?) Some websites recommend sticking the antenna on a square foot sheet of metal, but as this is Florida in the summer, I think our usual midday rainstorms might blow the whole over. I've also seen some mention of a wire groundplane - just a piece of wire cut to the proper proportion of a wavelength. This would probably stand up better to wind, but I can't find many specifics for this application. The cable and antenna are one piece, so I can't attack the coax shielding directly to the ground plane, but I assume the base of the antenna is a ground plate meant to lie parallel to the car roof and couple with it like a capacitor. Or am I wrong? Does the antenna need the only the mere proximity of a wire of proper length? I don't know.

I've seen a product advertised that looks like what I want, called Sputnik, but I'd really not buy anything else, especially when I could make it myself.

So I guess I need a small ferrous plate to stick to the magnetic bottom, to which I can solder the horizontal wires of the ground plane, but I'm not sure what lengths these need to be, how to position them, or how many to use.

I don't even know what wavelengths I'm dealing with. It's AT&T wireless, and "digital, not GSM", which I assume means PCS, on a Motorolla V60 color. Can someone tell me if I'm looking at 800 Mhz, or 1900, or what?

I considered making a parabolic reflector, but I know neither the wavelengths used nor the precision necessary. (Do I need to adjust it for the specific channels used, both for sending or recieving, or can I just use the center of the 1900 range as an estimate?) Anyway, it would be even worse with the wind than a flat sheetmetal counterpoise.

If the wire ground plane isn't feasable, could someone give me or point me toward some deteils on building a little yagi for cell phone use?

Any direction at all would be appreciated. I have ZERO experience with antennas or radio equipment. I have no idea if I'm even on the right track.

Thanks in advance, Isaac

Message-ID: <HXsIc.4824$dx3.37826@newsb.telia.net>
Source record: 92466

Hi all,
Anyone that have an idea about a wire antenna (folded dipole, trapped
something, etc.) that can be used on a limited space (e.g. on a smaller roof
11*6 meter)?
I mainly use verticals but need something for local (national) 80m QSOs.

cheers,
Hans / SM&#65533;IMJ

Hello Thomas,
Thank you for your info. I still have to put the gpa50 on a mast
against the wall. It is now on an experimental stand in the garden.
I am going to use a 35m rain gutter as a counterpoise as you suggested
to see how 80m will do.

A trap dipole can fit within that length if the ends (80 meter elements)
are folded, e.g.:

http://home.comcast.net/~jdegood/coaxtrap/

Dear Sir

We are looking for

Attenuators - 50 Ohm*GAAS MMIC 50Mhz*3GHz

Manufacturer = is = Advance Technology Division Alpha

Can you help ?

BR
Cordialement

Isaac,
Higher does more good than a large groundplane/counterpoise,
and yes, they're the same thing (sort'a). Almost anything will work,
metal sheet/plate, wire, foil, does 'mother's house have rain gutters?

Pending advice from the specialists, I'd be tempted to try a wire mesh groundplane - something like the stiff wire mesh used in (cake) wire cooling racks, with 1/2 inch mesh.

I don't think the size would be that critical providing the radius was similar to the length of the antenna. Connect the wire to the iron bar to which the antenna is attached.

Harry.

A ground plane need not be solid, as long as the holes are enough
smaller that the wavelength.

>I don't think the size would be that critical providing the radius was
>similar to the length of the antenna. Connect the wire to the iron bar
>to which the antenna is attached.
>
The size is not critical, but ideal would be a radius of 1/4
wavelength. For a 1/4 wave antenna without a loading coil, that would
be the same as the antenna length.

Do the calculation yourself, but 1/4 wave at 800 mHz is about 3.51
inches.

Mounting your antenna on a 7" diameter disk would be optimal. Perhaps
that will be easier mechanically to work with.

Happy trails,

Was this for a copper wire antenna? What happens when you choose
wire loss = zero?

For single-band 80m operation, a dipole with loading coils would work
just fine. If you have room for capacitive end "hats", it will decrease
the loading coil inductance required and increase the efficiency. The
ARRL Antenna Book has information on "off-center loaded" dipoles.

356. Log antenna mounting questions

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-12 15:04:54 UTC
From: Mike <km6ab@pacbell.net>
Message-ID: <qMxIc.9796$AT.4648@newssvr25.news.prodigy.com>
Source record: 92377

I want to vertically mount a VHF/UHF log periodic from the rear of the antenna to avoid mast interaction. (Greek mounting) This particular log is a dual boom feedline type and the booms extend to the rear several inches where they short together. My questions are, can I attach to the shorted end of the booms with a metal fixture for mounting to the metal mast? What would be an appropriate spacing from the rear of this antenna to the mast? The feedlind runs parallel with the ground side of the boom and I would like to use a ferrite choke balun on the feedline, is it best placed at the feedpoint at the front of the antenna or out where the coax heads away from the boom?
TIA,
Mike

I don't know if this would work very well for local QSOs because of
the vertical component, but this is what I intend to try at my new
QTH:

7M fishing pole with 2M PVC "waste pipe " extension then running
approx 11M wire horizontally from the top, giving horizontal and
vertical polarization components, this all fed against a buried radial
system of course. (Inverted L actually), for the price of some wire
and a fishing pole.

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <ccub4b$nq1$1@titan.btinternet.com>
Source record: 92380

New program XTL_SET.exe

About 60 kilobytes.

This program is both practical and educational. It is based on two loosely-coupled tuned circuits. There are several applications. The circuit of a 'crystal set' is illustrated. Tuned circuit L and C settings and the coefficient of coupling between the two coils can be varied from the keyboard while observing how signal power and voltage levels change at several points during a tuning-up operation.

The signal source is a broadcast transmitter of adjustable power output which radiates a groundwave. The radio path distance and ground path resistivity are also adjustable. A simple inverted-L receiving antenna of given length provides the signal for the receiver.

Download XTL_SET in a few seconds from website below and run immediately.

Malcom

I'd suggest that the antenna at the winch can be made more directional without increasing its height. But, you've probably thought of that. It would seem to be a good place to try a simple, small Yagi at the winch.

|measurements.
|
|The step from 2 wavelength to 5 wavelength showed gains consistent
|with doubling the length of the antenna size for many separations
|(e.g. 3dB gain, or thereabout). However, it appears that beyond 5
|wavelengths (considering my next cardinal point was a doubling to 10
|wavelengths) no further gain was observed as a general characteristic.
|
|If I were to judge this at the 180 degree spread and compare against
|ALL other designs; then the absolute greatest gain for a V design was
|observed to be slightly less than 4dB. In fact, the 2, 5, 10, and 20
|wavelength designs configured as simple dipoles barely differed one
|from the other (1dB at most, and typically 9.9dBi).

I must confess that I've tried to follow your path but clearly I'm
lost.

May I suggest that analysis at "180 degree spread", which I take to
mean a dipole, has no relationship to a vee configuration, other than
the wire length. If you will take each leg length and vary the apex
angle to the optimum, you will (should) find that the gain *does*
continue to increase with increased leg length, albeit at a
sub-proportional rate.

For each leg length there is an optimal apex angle. Leaving the angle
fixed and varying the length is *not* a fair test of gain vs. length.

Here are the results I obtained from a quick MultiNEC (NEC-2)
analysis. This at 144 Mhz with height = 20', Sommerfeld Gnd, with
average dirt. #12 AWG Al wire, 20 segments/WL, elevation angle = 4
deg. Source on the middle of a short (3 segment) wire.

Len. (WL) Ang. (deg) Gain (dBi)

10.200 30 19.84
20.193 20 21.97
30.188 16 23.06
40.185 14 23.70
50.182 12 24.10

These data seem resonable and consistant with my expectations.

Wes

I would put it at the feed and if possible run the coax through the
boom. If you can run it throught the boom, then you probably don't
even need the balun.

Source record: 92384
Cross-posted to: alt.cellular.tech,alt.cellular,rec.radio.amateur.antenna

If the groundplane as suggested doesn't do the trick, get an antenna that's designed to be mounted on the rear window, rather than the roof. That sort of antenna should be able to function properly without a ground plane. Another tip for either kind of antenna is to move the antenna in very small increments while watching the phone's signal strength indicator. A distance of a few inches can make a big difference when multipath propagation is present. If possible, find a general area where the signal strength isn't overly sensitive to antenna placement. If you can't, you either need to very carefully place it at a "sweet spot" (and hope the spot doesn't move when the wind blows), or use a directional antenna.

Roy Lewallen, W7EL

Of course, but with 180 degrees of spread it remains a basis of
comparison and as a basis of comparison, by varying the length of each
arm (measured in wavelengths, ï¿½ to accomodate matching) 2/5/10/20
wavelengths barely offered more than 1dB variation.

Logically, it follows that some angle less than 180 degrees will show
no radical departure from these observations. Continuing to decimate
the spread will exhibit some spectrum of variation with few radical
step-wise jumps. Once we enter into the sphere of conventional
expectations of what a V antenna "should" look like, it is unlikely
that we will arrive at a condition that springs out suddenly to take
up the difference between my data and yours.

> If you will take each leg length and vary the apex
>angle to the optimum, you will (should) find that the gain *does*
>continue to increase with increased leg length, albeit at a

I have done this about 80 times at 10 degree increments. As such,
gain is not a fluid thing (whereas drive Z is). Again, compared to
the dipole arrangement (180 degree spread at whatever arm length),
this then changes no more than 4dB above and certainly dives beneath -
again, all in part due to the variation in spread.

>For each leg length there is an optimal apex angle. Leaving the angle
>fixed and varying the length is *not* a fair test of gain vs. length.

I've done both in a full matrix - fairness is explicit.

Hi Wes,

I report my findings and you report yours.

I would note, however, that EZNEC+ is being used for its virtue of a 1500 segment ability (very necessary I can only suppose), and to which the program automatically prompts me when the segments per wavelength fall below a "conservative" suggested count. I also observed cautions about wires attaching at acute angles and practiced the remedy of a split source. There is no amplifying discussion as to what an "acute" angle is, and to what degree accuracy is impacted so I can only surmise that our differences are a difference in implementation.

Mathematically, an acute angle is less than 90 degrees, but experientially, this is hardly a radical separation. 5 degrees is admittedly acute, but I have no basis to confirm if the split source is adquate to achieve accurate results as the Help suggests it may be (or may not).

However, there still remains the rule of diminishing returns. Doubling the length must ultimately fail to perform. I am sure with scrutiny, the differences will reveal themselves in either pilot error, or implementation differences. I will examine further. Not much left to argue, is there? In other words, hardly worth 600 postings to gum into submission. ;-)

365. Long wire antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-12 21:42:26 UTC
From: James <jrapier@dcr.net>
Message-ID: <cBDIc.89$jY4.71@fe39.usenetserver.com>
Source record: 92387

I can barely spell antenna but I was thinking of putting up a long wire antenna outside for a shortwave receiver I have. My questions are these.

How long should it be?
Does it need to be vertical, horizontal or somewhere in between? Which is best?
What about guage of the wire? Radio Shack has a 70 foot stranded copper wire 14 guage with a couple of insulators as some sort of kit.
Could something like this be strung on steel insulated fence posts that are normally used for keeping livestock from wandering? That would put it close to the ground. I know that higher is always better.

I have a 35+ year old transistor Japanese shortwave radio that had a broken (and lost) whip antenna. I installed another whip with a little soldering, bought a generic ac adapter and lo and behold it worked pretty well. A little hum but acceptable. I thought that it would not cost a lot of dough to put an outside long wire antenna out there to receive some international stuff. It brought in some with just the whip but quality of signal should be much better in my estimation. I have lotsa room on the place here.

Any answers, tips or suggestions would be welcome. I thought if it worked out I might invest in a new shortwave receiver of some kind. Any suggestions as to that would also be appreciated. I have been thinking of a Grundig 800 but only done limited research so far.

Paul's idea for the inverted-L is good, but I have found that length of wire isn't effective use on 80 Meters. You could probably make it work but there is no telling how well it will work.

I had one once that was a similar arrangement. Fed at ground level it first went up about 30 Ft., then east for about 20 feet to a tree branch, and then south for the rest of the run. Overall it was about 96 feet long. I fed it with a small choke on 40 meters and added a series capacitor (250pF variable) on 80. A little pruning got SWR down on 40 meters and the variable capacitor took care of 80. I buried about 5 randon length wires (20-30 Ft) under the feed point.

Cecil suggested a loaded dipole and John suggested a trap dipole. Both give a shortening effect and the trap dipole gives you more bands to work. I used a home made trap dipole for 10-15-20-40 for many years and it worked great. Once it was set up there was no tuning on any of the bands. The only drawback is that in order to set it up right you should have a grid dip meter and a antenna analyzer on hand. You can do it with out them but it's much more difficult. It's usually easier to borrow the necessary equipment from a friend. I would expect that the tuning for 80 meters would be a little touchier than the higher bands.

To help increase your available space you could raise the center of the antenna in an inverted-v. Instead of having only 5.5 meters each side of center, a 5.5 meter mast would extend that to about 7.5 meters. Not a huge gain, but with the longer length, the coil for a loaded dipole could be smaller making it more efficint.

Hi Jerry,
yes had thought of going directional, but have some small
problem. Him up stairs, keeps changing the wind so we have to move the
winch about the field. Some times this can be by 180 degrees ! So we are
restricted to omni-directional...

Cheers, Malcolm...

That's a good good starting point James.

It is indeed, but one of the radio shack "kits" I had 40' up in a tree came down in a hurricane, and annoyingly (to me) worked almost as well lying on the ground. Because of it's length, it still worked in it's desired bands better than an elaborate fan-antenna of two long wires and transformer that did survive the hurricane. A long wire parallel to the ground will have directional aspects to it's reception. The steeper of an angle (but avoid more than about 60 degrees) the less directional it will be.

> I have lotsa room on the place here.

That also implies "quiet" from urban noise, and great for shortwave listening.

You would probably enjoy any of the used Radio Shack DX-series shortwave radios normally available on eBay. A lot less money and some are more capable than anything Grundig made. Of course the Grundigs will pick up nearly anything with the stock whip. But Grundig like many of it's kind were not made for real external antennas - and doing so does often just overloads the input to the detriment of all listening. The old Radio Shack DX series are made for long external antenna usage, as are all table-top/base type communications receivers.

Good listening.

Bill,
Did that test when I installed the antenna and there were no changes
at all points tested (checked every 45 degrees). Funny thing is that
I've seen insulators used and know why they're used ..... it just
didn't occur to me to consider them as I was fixated on using a
non-resonant guy length. Let's just call me lucky this time and
lesson learned for the future.

As to defining moderate.....I'm not biting 8-}

Malcom

It seems that you've got a problem on your hands. The base station must cover the hemisphere and have good gain at or slightly below the horizon. I suspect thats a very difficult pattern to produce with linear polarization. A QHA (helical) antenna might be an interesting antenna to try. But, it wouldnt be an easy antenna to develop and construct, like the J-pole or discone.

Hi Wes,

For this particular design (except mine is elevated 5 wavelengths), I
pushed for 1 degree resolution, with a split source, with tapered
segments (1023 all told) and I still fall short, but also well ahead
of my earlier reports:
18.5dBi @ 3 degrees w/3 degree lobe width

This analysis should be done in free space, not over ground. Propagation to the moon should avoid reflection from the ground, and in any case EZNEC's flat, infinite-extent ground model isn't representative of what the signal would encounter in real life.

One other comment. As a dipole gets longer, the lobes move closer and closer to the direction of the wire. Bending the dipole into a vee shape aligns pairs of the lobes so they point in the same direction, i.e., along the vee axis. That's why the optimum angle becomes less and less as the wires get longer, and why a dipole model isn't necessarily representative of what a long vee will do.

Isaac,
All these are acceptable suggestions, but if your antenna base is truly magnetic, an inverted 1-pound coffee can makes a perfect ground plane. Larger would be slightly better, but beyond that, "finding the sweet spot" is probably the best advice of all. Make sure that the antenna matches the band being used: I believe AT&T is 800 MHz for 'digital' in FL, therefore you should have a 800 MHz antenna. Do a google search for Cellular Yagis if necessary, but I find most of these at www.canyonriver.com, and www.antenna.com.

How about a discone? They cover a very wide range of frequencies and
are *relatively inexpensive. Probably on the order of $50 or so. The
simple Radio Shack model covers from about the FM broadcast band which
is well below the aviation band to over 440 MHz and are
omni-directional. There is a null directly overhead, but they seem to
do well. Otherwise I'd go with a ground plane and use a very large
diameter vertical element compared tot he regular size.

Hello Roy,

There are any number of problems with your comments:

>This analysis should be done in free space, not over ground.

The application demands ground as an inescapable reality of design.
Designing in free space, unless you expand upon your commentary, is
meaningless. In other words, the product of a free space analysis
offers no more insight that this blighted version. Your comments that
follow fairly shout this as a wholly undecipherable problem.

>Propagation to the moon should avoid reflection from the ground,

This has already been offered as a cautionary. However, as a
cautionary it says nothing about the impact of application aside from
the introduction of noise (ground temperature) which lies outside of
EZNEC's constraints. There would undoubtedly be issues of ducting,
much less diffraction at the air/space boundary - and these too are
within the domain of propagation modelers which is not what I perceive
EZNEC to be. However, propagation modelers do work from antenna
characteristics and it would seem this work is adequate to that
(anticipated) task. The propagation modelers I am used to seem to
expect ground considerations rolled into the antenna characteristics.

>and in any case EZNEC's flat, infinite-extent ground model isn't representative of what
>the signal would encounter in real life.

No doubt, but this still says nothing on which to hang a hat. The
valuations offered range from 10 to 22dBi. Are these values off by
3dB, 10dB, 100dB? Rather than having a good low angle response, the
actual response is straight up? What is the context of your warning?
If they are not representative do we have an unimaginable response?
If the EZNEC is sufficient for Rhombics at HF, certainly at VHF the
wavelength horizon is much further off and earth appears that much
flatter. Earth curvature exists for all applications and your
warnings would suggest no model is useful.

Very long rhombics and vees (for any frequency) cannot ignore the existence of ground. On the contrary, they rely on it, so a model including ground reflection is correct for this antenna. This includes the use of these antennas for EME in former days.

Apologies to Richard for not responding to the antenna files that he kindly sent across, a few days ago (other deadlines). The discussion has moved on in the meantime, so it makes more sense for me to jump in again here.

>One other comment. As a dipole gets longer, the lobes move closer and

>shape aligns pairs of the lobes so they point in the same direction,
>i.e., along the vee axis. That's why the optimum angle becomes less and
>less as the wires get longer,

That would have been my first point in response to Richard's findings. As a single end-fed wire gets longer, its radiation pattern becomes predominantly X-shaped, with the four main lobes moving closer and closer to the line of the wire itself. The optimum angle for a V-beam is chosen to make the main lobes of the two wires overlap exactly, so they reinforce as strongly as possible in the forward direction. If the V angle is kept constant and only the leg length is increased, the maximum obtainable forward gain will not be realized.

I don't have any of the classic references for optimum design of V-beams or rhombics to hand; but unless Richard and I are both doing it totally wrong, the V-beam does seem to show some reluctance to increase in gain by a whole 3dB for each doubling of the leg length (and the rhombic would do the same).

However, that doesn't detract from the reputation of the rhombic in particular as "the king of HF antennas" - if you have the real estate and can tolerate the fixed direction, the rhombic can give several dB more forward gain than almost any other practical antenna.

All of this prompted me to try to model the 50-wavelength-per-side rhombic that we used for EME, way back when. My recollection is that the included angle was 12deg, but the original notes are long gone.

EZNEC+ v4 predicts the spectacularly narrow main lobe that one would expect, and it also confirms the well-known finding that if you terminate the rhombic at the far end, the pattern changes from bi-directional to unidirectional but the forward gain also drops by about 3dB. However, 30-40 years ago it was believed that it is not important to terminate an extremely long rhombic "because most of the forward-traveling wave has been lost to radiation before it arrives at the far end." The model categorically negates that belief - even at 50wl/side, termination has much the same effect as for shorter rhombics.

Unfortunately the segmentation density in my model (7.5 segs/wl) is too sparse to be confident about the absolute value of the gain. Normally one should both increase and decrease the segmentation density to confirm that the predictions remain stable; but this is not possible because this enormous antenna has already used 1499 out of the 1500 allowable segments.

Since I can't be confident about the gain predictions, there is no point in quoting and discussing them here - we already chase enough wild geese in this ng.

Sorry, I don't have the time or inclination to get into another protracted "last man standing is the winner" diatribe. I'll leave it to the readers to evaluate what I've written and decide whether or not it makes sense, or whether they'll choose instead to be persuaded by your objections. Either is fine with me.

Roy Lewallen, W7EL

I'll answer for him, ...No and No.
Receiving loops aren't about signal strength they're about improved Signal
to Noise **Ratio**.
Not hearing 20 MHz WWV at the hours he said he was listening (late eve?)
means nothing as that band folds late at night or propagation simply may not
have been favoring a path between them at that time.
Try some Google-searching for receiving loops, lots of info.

Howard:

See, here's the problem. If those guys are tied to a metal mast on one end
and ground on the other, then you have no idea what the electrical length
is. And, if the mast is grounded as it is supposed to be, then the mast,
ground and guy form a loop which is dangerous even in the "non-resonant"
mode. And the SWR test is a very insensitive test. Although if forward
gain is the primary criteria, then you are likely OK, but on HF, where front
to back and front to side ratios are important, then guy reradiation can be
significant enough to mess those up without showing up on SWR.

And, receiving loops are about nulling out interfering signals.
Deep nulls has a loop.

Thanks for the additional info/perspective. I realize the SWR is only
a portion of the picture, though the only element I can actually
measure. F/B isn't much of an issue for me, from where I live most of
the directions I point my beam has the back pointing to the ocean.
The difficulty in adding insulators is that I don't do work on the
roof anymore & the handyman whom I've been using for such tasks is
pretty heavily booked these days. In any case, once he's free it's
not a huge task and with the worst case being no difference and the
best case being a better radiation pattern this is now on my list of
things to get done.

Thanks George and Bill for your input!

73,
Howard

Dumb question: how do you reduce noise without reducing the strength
of the signals you want to hear? How does the antenna know which is
which?

What makes some antennas "quiet."

A loop has directivity but if the noise is from the same direction as the
desired signal it doesn't help. However if the noise is 90 degrees off then
a loop will help.

OH, for Pete's sake. Loops are sensitive to the H vector. Wires receive the E vector. Most near field noise tends to be predominantly E field. But, that seems to only be effective up to 3 or 4 MHz, due to the wavelength factor, i. e. the near field shrinks as you go higher in frequency. Fully formed far field wavefronts of noise sources will be just like wanted signals, and unless some polarization difference is available, then directivity is the only way to improve S/N. Only in special circumstances can you see much improvement above 5 MHz due to near field/far field differentiation.

But, my point was that no improvement in S/N was reported in the original post. Only a decrease of noise accompanied by a decrease in signal. No relative comparison offered. Are we supposed to *assume* that the signals went down due to time of day, while the noise went down because it is a loop? Maybe the opposite is true? Not enough data to prove either.

Beams seem to "know" how to receive a signal from one direction while
ignoring noise from the opposite direction. My horizontal dipole seems
to "know" how to ignore vertically polarized noise.

395. CD Player Receives FM Station

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-14 02:03:41 UTC
From: uceftcgov@webtv.net
Message-ID: <4670-40F4947D-729@storefull-3172.bay.webtv.net>
Source record: 92416

Sometimes at night I listen to my portable CD player, plugged into the wall outlet, using a set of headphones. I receive a local (as yet unid.) FM radio station. The signal is faint but clearly audible and I turn up the volume to drown it out to hear the CD. Anyone one else have this happen? Is it the power cord or is it the headphones' cord acting an antenna?

Thanks!

Yes, more likely its an AM station, they just need a diode to rectify on, FM needs a discriminator, but CD may have somenting of that sort in it.

Say, for purposes of illustration, that the near field ends at 1 wavelength.
At 2 MHz, that is very roughly 530 feet . At 14 MHz it is about 64 feet.
At 30 MHz, it has shrunk to ~32 feet.

> -- Why would the near field end at 1 wavelength? It ends
when the wave front arriving at the receiving antenna becomes planar. ie, to function efficiently in the far field, the receiving antenna needs to intercept a planar wavefront. That is, the individual rays need to be arriving in parallel. If the distance between antennas is very great, that is very nearly the case.

If the capture area of the receiving antenna is great relative to the distance to the source, the received energy arrives as non parallel rays that basically reach the receiving antenna out of phase with each other and partially cancel. So, the gain of antennas measured in the "near field", where the received energy is not a planar wavefront, will be in error. The distance to the end of the near field is highly dependent on the gain of the antenna and with UHF and SHF antennas often exhibiting very high gain, their near fields can be and often are very large.

The power collected by a receiving antenna within the transmitters near field is very nearly constant with distance. In the far field, recovered power varies inversely with the square of the distance.

Balanis divides the near-field region into two parts: a reactive near-field
R<0.62 square root(D^3/Lambda) where D is the largest antenna dimension,
Lambda is the wavelength, and R is the distance from the antenna surface,
and a radiating near-field region R<2D^2/Lambda. The far-field he defines as
anything greater than 2D^2/Lambda. He gives exceptions to these rules, so
take them with a grain of salt.

Yes, but does your small, inefficient, shielded loop improve the
signal-to-noise
ratio in the directions of its maximum gain over say, a non shielded loop?
Moreover, how do you get your beam to be less sensitive to noise in its
favored direction? Are you robbing Peter to pay Paul?

In the UK, we're not supposed to use 'unproved' commercial equipment in
modern cars (although I think we can still use homebrew). This is
supposedly to avoid the risk of interfering with the electronics
(although I can't really think why 'approved' equipment should be
better). It's all to do with being a part of the European Community, and
the rule-making bureaucrats in Brussels.

Obviously, the real solution to the problem would be to improve the
immunity of the car electronics (which costs), but you now have a good
reason to justify not doing this.

In the UK, we pay a TV licence. There are detector vans which track down
offenders. The obvious way was to look for the radiation of the local
oscillator in the tuner. However, a radiating local oscillator is a 'bad
thing' because it interferes with things. With modern sets, it's
probably easier to look for the rubbish from the switch-mode power
supplies (which is often worse when the set is in standby).

It used to be said that the TV manufacturers were actually willing to
improve their designs in order to reduce the radiation, but were
pressured not to do so! I'm not sure how true any of this is. I've a
sneaky feeling that costs again come into it somewhere.

Cheers,
Ian.

|the signal would encounter in real life.

Not exactly, but often good enough, especially for comparative
purposes. The reflector at the other end isn't a smooth ball of green
cheese either but it still looks pretty smooth at rf. [g]

True; I didn't report it but it is there. Typically at most
frequencies the desired signal is reduced 1 to 2 S-units with respect to
the whip antenna (strong ones) or my high long wire weaker signal...156
feet AWG 16 up 45 feet fed off center w/ a 4:1 balun) but the noise
level is reduced by anywhere from 3 to 6 S-units...a very! worthwhile
tradeoff. Exact quantitative measurements are not possible on the
Sat800 RCVR because you can't turn off the AGC. My understanding of why
the shielded loop performs this way is that near field noise is
cancelled while far field signal is only attenuated by some factor
relating to capture area. In my temporary rooftop mount I was unable to
easily check out the effect of broadside null.

|I don't have any of the classic references for optimum design of V-beams
|or rhombics to hand; but unless Richard and I are both doing it totally
|wrong, the V-beam does seem to show some reluctance to increase in gain
|by a whole 3dB for each doubling of the leg length (and the rhombic
|would do the same).

Why would this not be so? The remote parts of the antenna have less
energy to radiate.

As the antenna becomes longer, it becomes less a standing-wave antenna
and more a traveling-wave antenna. Kraus discusses Vs, terminated in
their characteristic impedance, that offer increased front-to-back
ratios because the reflected wave is suppressed.

It is easily observed that as an unterminated V becomes longer, there
is a modest increase in the front-to-back ratio and the real part of
the feedpoint Z becomes nearly constant. The loss in the wires, both
resistive and radiated, suppresses the reflected wave, in effect,
self-terminating the wires. I believe that if it was not for this
loss, the V would be totally bi-directional and the gain would be
proportional to length.

Kraus offers another V that has conductors of "considerable thickness"
that produce a similar front-to-back improvement.
|
|However, that doesn't detract from the reputation of the rhombic in
|particular as "the king of HF antennas" - if you have the real estate
|and can tolerate the fixed direction, the rhombic can give several dB
|more forward gain than almost any other practical antenna.
|
|
|All of this prompted me to try to model the 50-wavelength-per-side
|rhombic that we used for EME, way back when. My recollection is that the
|included angle was 12deg, but the original notes are long gone.
|
|EZNEC+ v4 predicts the spectacularly narrow main lobe that one would
|expect, and it also confirms the well-known finding that if you
|terminate the rhombic at the far end, the pattern changes from

|bi-directional to unidirectional but the forward gain also drops by
|about 3dB. However, 30-40 years ago it was believed that it is not
|important to terminate an extremely long rhombic "because most of the
|forward-traveling wave has been lost to radiation before it arrives at
|the far end." The model categorically negates that belief - even at
|50wl/side, termination has much the same effect as for shorter rhombics.

I'm surprised that you're seeing this. My modeling of even relatively
short rhombics shows that removing the termination does not make the
pattern symmetrically bi-directional and likewise I don't see anything
near a 3 dB change.

>tradeoff.

Presumably, the comparison is loop vs. these others. It is not
explicit and that is one of the problems of reporting and subsequent
interpretation - hence the observation in the double quote above.

However, the "issue" is more has anything really changed? A loop
(dipole) compared to two verticals. Arguably the so-called off center
fed long wire is presumed to be a dipole, however (again poor
reporting) nothing says of this antenna being choked. Lacking that
choke offers every inducement of Common Modality (the antenna is,
after all, fully and admittedly unbalanced by its very description).
Common Modality is ever bit a noise hazard as any vertical (is
supposed to be - another nightmarish fantasy under the bed).

Hence, any perceived boon of noise reduction comes as a consequence of
the loop's faithfully performing as a - dipole! Wonders never cease.

>Exact quantitative measurements are not possible on the
>Sat800 RCVR because you can't turn off the AGC.

I don't know how this got started as a unnecessary evil - AGC is what
drives the S-Meter. AGC is only an issue if you want to derive signal
strength via modulation levels - which nobody here does anyway.

>My understanding of why
>the shielded loop performs this way is that near field noise is
>cancelled while far field signal is only attenuated by some factor
>relating to capture area. In my temporary rooftop mount I was unable to
>easily check out the effect of broadside null.

Tom has posted in this thread very simple metrics to obtain just what constitutes near field. The incantation of near/far fields belies simpler explanations. If there is any issue of noise that relates to its nearness, it follows that you are the source. You being the source means that you also have the capacity to correct (and building a magic antenna is possibly the most superstitious response to that problem). The loop simply has less coupling (and less signal - that means there is a constant of proportionality in S/N) than a full sized dipole sitting over this noisy domicile. I have a random wire antenna that passes within 2 feet of an 80W Fluorescent fixture with a humming ballast. I barely pull in S-1 worth of noise and a loop would stand to do worse at that same distance. If I find that little noise troublesome, I turn off the noise.

The fact that the shielded loop performs as a dipole is proof of its efficient construction (many fail to achieve even this). There is very little more that can be said about its qualities short of its loss of sensitivity.

I need to increase the range on my Heath-Zenith wireless doorbell.

I believe it operates on 315 mHz.

The antenna in the remote/transmitter looks like loop of length 1.5".
The antenna in the ringer/receiver is a wire 1.5" long that ends in
the breeze.

It would appear safest to lengthen the wire in the ringer/receiver to
around 7" but I do not understand why the manufacturer just didn't
make it longer in the first place.

Adding a random length to an antenna is not the way to improve its
performance. Bigger is not always better.

A more directional antenna, tuned for the right frequency/wavelength,
would solve the problem legally, but could cost more than the device
you own.

You might also consider what kind of structure is in between the two
points. Too much metal in the construction will interfere with any
radio waves.

Happy trails,

Depends upon the source of the noise. I remember a small shielded loop
being effective against localized electrical noise in my college dorm.

Many claim this, but I didn't see it when I compared them. I found a shielded coax loop just as susceptible to local, and not so local noise, as a non shielded loop assuming both are balanced. This is not counting the feedline, or any common mode currents unbalancing the loops. Both are capable of very sharp nulls. No difference really, and both are good at nulling a noise source. But a shielded coax loop quieter than a regular loop? I don't see it. It's not the loop itself, or having a shield. It's the keeping of good balance. The shielded loop design and method of feeding forces a good balance. But if you have a regular loop that is also just as balanced, I maintain it's just as "quiet". To me, this "shielded loop being quieter" theory is an old wives tail of sorts. My two favorite MW loops are both unshielded. Ones a 16 inch dia circle with 12 turns, and my big one is a diamond with 44 inches per side. "5 turns". Both are on floor stands indoors, and rotate.
I've tried using shielded coax loops, and I saw no reduction of noise. I've also compared using both shielded and non shielded coupling loops to feed the loops. Again, no difference in noise levels. MK

No one said it would. You should read more slowly.

>If you had said "To keep your neighbors' buttons from ringing your
>bells," that might have been valid.

No, I was responding to the bit about "why the manufacturer
just didn't make it longer in the first place" -- the manufacturer
intended that the receive range -- on all units -- be short enough to
avoid this problem. If he made it longer, everyone might ring bells
for a couple of houses on either side, as well as their own.

This pretty much squares with an article on shielded loops written by
Glenn S. Smith of the Georgia Institue of Technology in _The Antenna
Engineering Handbook_. He says the shield enforces symmetry so that
the pattern doesn't suffer, and that's what it's supposed to do. No mention
of noise at all.

Mark, I fully agree.

The amount of unscreened signal picked up by an unscreened multi-turn loop
is negligible compared with what is picked up by the action of the loop
itself and then magnified by the Q of the loop. The unwanted signal cannot
possibly be more than that which would be picked up by a very short vertical
of height equal to the loop diameter and would probably be less.

If there's a problem it is more likely to be picked up on the feedline which
is not influenced by the presence or absence of a screen around the loop.
If something must be screened then screen the feedline.

Loop screening is needed only when precision direction-finding bearings are
being taken with an in-the-clear, precision-constructed, large loop.

That's what the ARRL antenna book also claims. They talk about shielded loops in the context of direction finding antennas. The shield is supposed to make the antenna balanced with respect to ground, and retain directionality. Also, and I don't recall if anybody mentioned this, but the shield can not be closed around the circumference, and the maximum wire length is on the order of lambda/10. The loop is tuned to resonance with a parallel capacitor.

It generally is screened already (coax) but it does need some kind of
balun.

It's amazing how many loop designs are paranoid about balancing and
screening the loop itself, but then connect the coax in a totally
unbalanced way. The result is a beautifully balanced loop in parallel
with a vertically polarized random wire.

Hi Ian,

Some old wives even extoll the virtues of screening the coupling loop of a magloop.

It may be kindly said that screening a loop at least does no harm.

But the screen greatly increases capacitance across the loop and thereby restricts the tuning range of the proper capacitor. The number of turns has to be decreased. Or in the case of a single-turn loop its diameter must be reduced which also rapidly reduces receiving sensitivity.

I've a feeling it also degrades loop Q. It certainly can't improve it.

Reg, G4FGQ

William,
I have done some work on local QRM reduction during the last
few years. Summarized on:
http://home.plex.nl/~jmsi/
Most important is avoiding any coupling with the coax/feedline.
With small magnetic loops this is easy to accomplish and my
guess is that this is why loops are less susceptible for local QRM.
That is why I choose small loops instead of small dipoles.

Hi Rick -

You might also want to consider Cable X-perts CXP1318FX.
The performance is similar, and it's probably more flexible, and cheaper.

But they can also sell you the LMR400.

http://www.cablexperts.com/cfdocs/cat.cfm?ItemGroup=1&itmsub=0&bskt=0&USA_ship=1&c=0

But . . but . . so the cop punches the button, turns loose a monster
burst of RF and the perp's engine sputters out. What prevents the RF
from also shutting down the engine in the Looney Van? The cops will be
issued Looney Vans equipped with RF-proof 1956 Stromberg carburetors
or what?? That would thrill the EPA and the EU envirofreaks no end . .

Sometimes I wonder about these academics . . last month it was the
University of Rhode Island . .

I've always bought coax on ebay and the prices are always cheaper. You have to make sure it's new and it often comes with your choice of connectors already installed.

It does no harm to look there, but be sure you really know what you're looking for as there are no returns:>:

Good Luck

What prevents the perp from having his own RF gun? Are the cops
going to be driving 1960 Pontiacs?

After reading many review of the Isotron antennas (the ones which look like birdfeeders!) I had bought a 40 meter version as well as the 10/15/20 combo.

Put the 40 meter version up on a 12 foot mast, super easy to tune, worked great, 1.2:1 SWR across the 40 Meter CW portion of the band without the use of a tuner. Made better 40 meter CW contacts on the Isotron than on my dipole, I still can't believe how good that "birdfeeder" works.

Well I'm putting the 10/15/20 combo version together and its been more of a problem. Can't get a good SWR, about 2:1 is the very best I can do on any of the bands.

Each antenna has an SO259 connector and each antenna is connected in parallel via short piece of twinlead. So I don't know which antenna I really should connect my coax to, the 10, 15, or 20? Anyone have experice with the 10/15/20 combo who can offer some suggestions....

445. Stealthy 'dual-CP' emissions (more TV channels)

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-17 04:37:57 UTC
From: VE1BLL@rac.ca
Message-ID: <8a615218.0407162037.6170399a@posting.google.com>
Source record: 92366

FYI:
CP = Circular Polarization
RHCP = Right Hand CP
LHCP = Left Hand CP
FYI = For your information ;-)

New concept...?

If one were to arrange for the emission of a RHCP signal, and the same - but inverted - LHCP signal, then the resultant composite 'dual-CP' emission should be more-or-less undetectable by any linear antenna. This is because a linear antenna in any orientation would respond equally to both circular senses and, since one sense carries the inverted signal, they'd cancel out (within the linear antenna) to the degree that balance and symmetry is maintained.

Only an appropriate CP antenna would be able to extract the 'dual-CP' signal. Obviously - use a more complex 'dual-CP' antenna system to extract both senses, suitably de-invert one, and then combine at RF for purposes of improving S/N by +3dB.

Since the RHCP and LHCP senses are inherently isolated from each other, there doesn't seem to be any reason why such a 'dual-CP' signal couldn't be easily generated and extracted. The RF hardware implementation is fairly obvious (nearly trivial).

Also, that such a 'dual-CP' signal would be more-or-less ignored by a linear antenna also seems obvious.

The most immediately-obvious application is a 'stealthy' transmission, at least until someone shows up with a bent whip on their receiver.

Interesting, but not that exciting.

Then the penny drops...

This concept could be applied to satellite broadcasting (for example) to provide ANOTHER (3rd) downlink polarization. In other words, for FSS satellite (for example) where they already use two linear polarizations (H and V) to double their effective bandwidth, this 'dual-CP' transmission technique could provide a '3rd axis' (thereby increasing the total effective bandwidth by another up to +50%).

The satellite example has the huge practical advantage over the 'stealthy' example in that the receiving station is co-operating (if his antenna is defective, he'll get it fixed). This co-operation would help to maintain isolation of the 3rd axis.

The isolation won't be perfect for various reasons (for example, perhaps Faraday rotation through the ionosphere would upset the CP balance). But the isolation doesn't have to be perfect for the new axis to provide valuable RF real estate.

The same sort of concept could also be applied at the baseband level thereby reducing some of the RF hardware while providing the same benefit on a transponder-by-transponder, narrower bandwidth, basis. It's an option to further explore anyway.

Any comments or technical objections?

de VE1BLL (Jeff)

The sum of LHCP and RHCP fields of equal magnitude is a linearly
polarized field. The orientation of that linearly polarized field
depends on the relative phases of the LHCP and RHCP fields.

Definitely! (I'm always a sucker for VHF test equipment.)

H-P used to make one of these, in the form of a very deep trough-line with massively braced side castings. There was also a 'lite' copy in the old ARRL VHF Handbook.

If you can minimize the residual SWR (the variation in probe readings along the line when terminated in a precision 50R load) and other sources of variability, then you'll be able to make highly accurate vector impedance measurements at VHF.

Ian

This line is showing a reflection of 1/10th of the incident voltage. I
am not inclined to refine the mismatch inherent with this construction at
this time. I dont require this line to be a "lab standard". I might try
to minimize the reflection later.
I tapered the line from 2 inch OD down to BNC in only about 3 1/2 inches.
And, I made no attempt to account for the teflon discs used to hold the
center conductor in the center of the line.
I dont even have enough stuff to evaluate the adapters from N to BNC. I
assume the reflection at 137 MHZ is acceptable to me. I sure cant do
anything about adapters from N to BNC anyway.

The slotted line does provide a flat voltage at the probe for all points
along the slot when it is terminated with the BNC 50 ohm load. Nothing I
have here is quality test equipment.
I'm impressed with the fact that I was able to measure load impedances
pretty accurately when they are outside the 1.5 to 1. VSWR circle.

It impresses me that a slotted line can be so easily constructed with
"Home Depot" stuff and still give alot of information on load impedance..

I seem to recall an indepth analysis on the AntennEx site showing that it
was the shield on the coax that did the majority of the radiating. A simple
proof would be to change the coaxial feeder length or how it is physically
run and look for VSWR changes.

Hi Jim -

It's not clear (to me) exactly what you mean by "Product Review section;"
but I checked the reviews on eHam.net.

I was surprised to find that X-perts quality control on connectors was
criticized by a number of hams. Mine have all been fine; but I do place
some weight on eHam reviews.

I don't know whether Rick is looking for ready-made assemblies, or just
bulk cable. And I don't know if DavisRF offers ready-made assemblies,
or not. But my current thinking is that either the 1318 cable from X-perts,
OR the Bury-Flex from Davis would be good cable, as such.

As for assemblies, the X-perts stuff is MUCH better than the no-name,
cheap assemblies I previously bought from HRO. But the eHam reviews
have convinced me that X-perts has (or had) some serious quality control
problems with their connectors. It also sounds like they didn't take very
good care of their customers when problems turned up.

459. Contact Question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-17 14:27:16 UTC
From: Doug Birky <dgbirky@voyager.net>
Message-ID: <10fidrdflcpnnda@corp.supernews.com>
Source record: 92280

I am new to HF having just passed my General and code tests. I am putting up a dipole the will be running due East/West at about 40ft. I really have no other options for installation and cannot run it North/South. I am in lower Michigan. My question is will I be able to make any East Coast contacts with this? Specifically, I'd like to be able to monitor the W1AW bulletins, code runs etc. I am interested in contacting the Southern states, but would like to know if the East will be accessable.

Thanks in advance,
Doug Birky

>
> Dale W4OP

Originally where I had the 40 Meter Isotron located I was using about a 50' coax run (RF-9913). I the moved the antenna to a different position and had to add about 25' more of coax. The additional coax caused SWR to jump from about 1.2:1 to 1.4:1. A quick returning of the "tuning rod" on the antenna brought it back to 1.2:1

Last night I was doing more playing with the 10/15/20 combo, was able to get the 20 meter size down to 1.2:1 and had about a 300 KHz bandwith to say under 2:1 SWR so I'm happy with that. But still can't get the 10 & 15 meters to do any better than 3:1. It possibly might be the location of the ant as its pretty close to some electical house wiring?

congratulations.

and yes, at 40' the dipole will not be very directional except maybe on 17m
and up, and even there you will still hear, probably just not as loud.

It may or may not be accessible. However, you can dramatically improve the situation by setting the dipole up as an inverted V. As such, it pretty much becomes omnidirectional.

463. Circularly Polarized for LPFM

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-17 15:28:59 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <10fihd5h8vl6486@corp.supernews.com>
Source record: 92284

Dear Group:

A popular antenna for LPFM stations is an antenna that I call an OI antenna (because of its appearance). It consists of about 0.25 wave lengths (WL) of thick wire shaped into a circle [the O] in the horizontal plane with about 0.125 WL of thick wire in the vertical plane connected to each end of the circle [the I]. In other words, it is essentially a 0.5 WL dipole with one leg extending from the center to the left in a horizontal circle that then points down while the other leg extends to the right in a horizontal circle that then points up.

Commercial examples are the Telecom TFC1K and the well built Dielectric DCR-L. Most often, two of the antennas are used vertically spaced by 1 WL and driven in phase. All venders characterize the antenna as being circularly polarized.

1. What is (are) the conventional name for this antenna? I have not been able to find it in any of my references.

2. When I model one bay of the antenna I find that almost all of the radiation is vertically polarized. This is not at all surprising in view of the symmetry of the horizontal element [the O].
What might I be doing wrong?

Speculation: I may not have the dimensions correct though the antenna I modeled is resonant at 94 MHz. It is possible that venders are equating omni-directional-in-the-horizontal-plane with circularly polarized.

I have an EZNEC file that I will send to anyone who wishes it.

The impetus for these questions is a determination of an appropriate offset of these antennas from a large diameter tower.

Thanks in advance for your insight.

464. Buried ground wire, insulated or bare?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-17 15:30:16 UTC
From: Bob Miller <bxmillerNoSpam@texas.net>
Message-ID: <amgif0dptot85r367e2sj0ebo74s4fjhkv@4ax.com>
Source record: 92285

I can't find this in any of my books, so thought I ask the group:

For my general station ground, I have a copper pipe that goes down
about one foot -- then hits rock or limestone or whatever.

I'd like to enhance the pipe with a few buried radials. I happen to
have a 500' roll of 14-guage stranded *insulated* copper wire. Will
the insulation keep the wire from becoming "one with the dirt"?

Or should I go buy some bare solid copper wire?

Tnx,

Bob

This has been hashed over many times. A google search will provide all
the details.

Bottom line:

If you want a DC ground, bare wire or bury your ground rod in a trench.

If you want a RF ground, it doesn't matter.

Commonly called a "ring-stub" element. It was one of the earliest methods of adding v-pol to an omni h-pol antenna of the "ring" design, popular before CP was authorized by the FCC.

> 2. When I model one bay of the antenna I find that almost all of the
> radiation is vertically polarized. This is not at all surprising in
> view of the symmetry of the horizontal element [the O].
> What might I be doing wrong?

There is a considerable h-pol component from the portion of the element in the horizontal plane. But as h-pol and v-pol do not have the same radiation center from this design AND the horizontal part of the radiator generates a v-pol component for elevation angles not in the horizontal plane, the axis of net maximum v-pol radiation in a ring-stub element is not located in the vertical plane.

The PDF slide show (Paper 10) at http://rfry.org includes NEC2 pattern studies of this and three other types of FM broadcast transmit elements, showing the differences in their free-space surface patterns without the effects of the tower.

Paper 6 at http://rfry.org shows some of the affects of two nearby tower structures on sidemounted FM broadcast transmit elements for one set of conditions. Unfortunately the patterns cannot be applied to any other conditions.

The best approach is to have the patterns measured by the antenna OEM, using one or more mounting configurations preferred or possible in the final installation.

thats what he's saying. inverted V's are a bit less directional than true straight dipoles... and usually easier to put up.

Hello, Ian,
here's a little trivia concerning slotted lines you might find interesting. I developed all the antenna systems that flew on the World's first weather satellite, TIROS 1, in late 1957, which flew April 1, 1960. The system operated on four different frequencies, two around 108 MHz and two around 235 MHz. Circular polarization was required, and was achieved using four crossed unipoles working against the body of the satellite. Each unipole used a 1/4wl sleeve for the high-frequency portion with a coaxial extension for the lower frequency, decoupled by the sleeve for the higher frequency. The sleeve portion was was developed to yield a 50 + j0 terminal impedance that included the mutual impedance of the extended portion. The extension portion was developed to provide as low an SWR as possible at the lower frequency. The coupling system for feeding the four radiators with four transmitters simultaneously was designed in stripline.

Now, getting to the point of the story, the development of the radiating elements was performed before there were any network analyzers--I performed ALL the work using only a slotted line for hundreds and hundreds of measurements. The line was an HP-805, that couldn't cover the frequencies involved, so I used 4:1 scale modeling at 432 and 940 MHz. The radiator development was done using a single element over a ground plane, with the spacecraft modeled with a 4:1 half shell mounted on a 4' x 4' aluminum plate for the ground plane.

If you have a copy of Reflections II you can see a picture of my lab setup at the RCA Laboratories in Princeton, NJ, showing the ground plane and the HP-805 slotted line. Incidentally, in 1957 there were no hand calculators either--my calculations from the line measurements were all made with a slide rule. Just

picture the amount of work involved using such antiquated equipment compared with what we could do now using today's more sophisticated instrumentation.

Without giving the problem any serious mathematical or physical thought, only knee-jerk intuition, IMO, if a radiator suitable for radiating CP of either hand were fed with equal signals leading to both RHCP and LHCP simultaneously, I agree with the poster above that complete cancelation would result, and there would be no radiation.

This is why a linearly-polarized antenna could not receive any energy. (har har)

That's the irony of it: if they'd been able to connect modern computing
power to a simple slotted line, they might never have bothered to invent
the network analyser :-)

Actually, slotted lines and computers might just about have overlapped.
I'll bet that, somewhere on an 8-inch disk in a forgotten landfill,
there are programs that say:

Connect Short to Slotted Line and Press Enter >
Enter Voltage >
Connect 50 ohm Load to Slotted Line and Press Enter >
Enter Voltage >
Connect ...

They should be so lucky! In 60, Pontiac was building a race rep, and a friend of mine bought a 3/4 race special factory package Bonneville. It may have been heavy, and the front hood looked like the horizon, but you could chirp the tires at 80 MPH going into 4th! IIRC, also about 6 MPG. It would make one fantastic freeway cruiser.

Maybe you haven't noticed it, but government regularly exempts itself from
the picky regulations that they impose on the general populace.

It's not the carb that's the RF sensitive element, it's the Engine Control
Computer which the zappers attempt to toast. That means that the ideal
immune vehicle would be about pre-1980, with a Kettering ignition system.
However, the 70's cars were notorious for trying to reduce exhaust emissions
with pneumatics, thermal delays, and other non-electronic systems. Those
systems created balky, stall-prone engines, so we need to move the date back
to about 1970.

Yes, Ian, you COULD have driven a tank across it, it was constructed of a massive hunk of aluminum with reinforcing segments to prevent physical distortion. It measured better than 1.02 SWR with a precision 50-ohm resistive load.

>Actually, slotted lines and computers might just about have overlapped.

Probably so, I still have a few 8" disks lying around, just so I can show and tell my great grandchildren (and I have five) what the early days of computers were using for memory.

I'm going to scan the pic in Reflections and email it to you in JPEG format.

Yes you should have better reception of W1AW on an inverted V dipole that a straight dipole when you are limited in picking the orientation.

By the way, I'm a YL not an OM.

One of my assumptions is that the RHCP and LHCP can operate in complete isolation of each other. DBS satellites (for example) use RHCP and LHCP to double their bandwidth, just like FSS satellites use H and V. I have not heard anything about the DBS RHCP transponder having to worry about the LHCP transponder. I haven't heard any mention of nulls suddenly appearing and disappearing in the downlink passband as the two senses happen to coincide, out of phase. I haven't heard about the CP being converted to linear and causing interference (at -3dB) in the other CP mode.

I assume that the two CP signals have no knowledge of each other. The hardware can be designed (easily) to maintain that isolation - imagine the two transmitter hidden from each other and the signals just happen to be headed in the same direction. In other words - for purposes of argument - it doesn't have to be the same antenna.

It just so happens that, for this 'dual-CP' concept, the two CP signals happen to be the same but one is inverted. They don't have to 'know' about their evil mirror-image twin.

If they cancel out, then where does the energy go? Make it a mega-watt each and follow the smoke. If they combine in the vacuum of space, where is the smoke?

Appreciate your comments...

Hi Jeff, my age is showing. In my knee-jerk reaction I stupidly thought of applying the RH and LH sigs from the same source. Of course your concept works when the signals are supplied from two different sources. The two signals are totally oblivious to each other.

I know this is true, because it's exactly the method I used in developing the antennas for TIROS 1, the World's first weather satellite. The circuit concept I used there comprised a four-port hybrid ring, or rat race. The two transmitters fed two opposite input ports. Each of the ouput ports fed a two-port balun, each balun port feeding one terminal of a dipole. However, the line from one of the output ports had a 1/4wl extra length, and the dipole fed from this output port was oiented 90ï¿½ from the other. With this arrangement, the radiation of the signal entering one input port of the hybrid is inherently RHCP and from the other is LHCP. The signals from each transmitter were received on a linearly-polarized antenna at any orientation angle, with no mutual interference.

If you'd like I can send you a copy of the circuit diagram in jpg format. This coupling system was fabricated in stripline, so if you'd like, I'll also send you a copy of that. Actually, the total system comprised the use of four transmitters, with each pair operating in two different frequency bands. The total coupling system fed all four transmitters simultaneously into one antenna.

Please let me know if you'd like me to send the stuff.

Some time ago, I stated that at any point in space there's a single field, and that we can split it into various components to suit our analytical needs. But the way we choose to split it or, conversely, the way it was created (from a single source or polarization, or multiple ones) doesn't alter the nature of the field in any way. I'm not sure if what I said was simply disbelieved or whether it was ignored -- the end result is the same.

The total field you get from simultaneous RHCP and LHCP waves is simple to see by using the index finger of each hand to represent the instantaneous orientation of the E field from each of two waves. Point the index finger of your left hand downward and the index finger of your right hand upward, knuckle-to-knuckle, so the fingers make a vertical line extending from one fingertip to the other. The left index finger will represent the LHCP wave and the right index finger the RHCP wave. At the beginning instant that we're illustrating, they're out of phase and sum to zero. So the field at that point and that time is zero.

Now rotate your left finger 45 degrees CCW and the right finger 45 degrees CW, to represent how the fields are oriented 1/8 period later or 1/8 wavelength away. If you add the two finger "vectors", you find the result is a field that's horizontal, pointing to the left, and 1.414 times the length of one finger. Rotate the fingers another 45 degrees, the left finger CCW and the right one CW. Now they're both pointing to the left, and the sum is a horizontal field with magnitude equal to 2 fingers. If you continue this process, you'll find that the sum of the two fields is always horizontal, and it oscillates between zero and two fingers in instantaneous amplitude. It is, in fact, exactly the same as and entirely indistinguishable from a horizontally polarized wave coming from, say, a dipole. You can reach the same conclusion mathematically from the equations I posted a few weeks ago.

If you run the same experiment beginning with the fingers in phase -- both pointing upwards -- you'll get a purely vertically polarized wave. And with other starting phase angles, you'll get linearly polarized waves of other orientations.

No magical energy distruction or disappearing takes place -- it's all accounted for. And you can receive it just fine with a dipole.

Make the "dipole" multiple wavelengths long. The major lobes will move
toward the ends of the "dipole". (I say "dipole" because it is then
actually electrically a polypole.)

My 1972 VW squareback had true electronic fuel injection controlled by a transistorized analog computer (made on a sturdy PCB with discrete components and tucked into a rear fender well). It did have a Kettering ignition system, but on 15 meters my HF rig would stop it dead in its tracks by shutting down the fuel injection.

The reason I asked is that I used to have one of those as a company car.
As I remember, it was 455 in^3. I used to drive the radar cops bats*it
by slowing down to 70 when approaching an overpass and then going 120 in
the straightaway out in West Texas. The radar cops *always* parked just
on the other side of an overpass in 1960.

That is because the nulls occur orthogonally to (and not along) the
path. ... At least in the sense of your thought-experiment.

>passband as the two senses happen to coincide, out of phase. I haven't
>heard about the CP being converted to linear and causing interference

And possibly for a very good reason: the earth is thousands of miles
away where the subtended arc of the service region precludes more than
a few degrees difference in path length/delay. The initial phase
balance is preserved by geometry.

>If they cancel out, then where does the energy go? Make it a mega-watt
>each and follow the smoke. If they combine in the vacuum of space,
>where is the smoke?

Hi Jeff,

This is just a tarted up version of the multipath phenomenon otherwise
called the Fresnel Zone which, in turn is an example of the optics
display of Newton's rings. If the earth were flat (a presumption of
modelers), then you would observe concentric rings around the service
area that were alternately hot then cold. The earth isn't flat, but
that doesn't cast this effect into the unfathomable, it simple
distorts the progressively outer rings' widths.

Possibly. If you have the arrl antenna book, see page 7-3, comparing
an inverted v to a flat-top dipole. The flat-top has an oblong
radiation pattern; the inverted v, the pattern is pretty much
circular.

Same thing, page 20.11 of the arrl handbook, which also mentions,
tho', that the inverted v lobes have 8 db gain, less, than the
flat-top.

Sounds like it could be a wash...

You're absolutely right, Roy, I confess I shot without aiming properly. It's been many years since I worked with CP, and I now remember going through the same exercise that you presented above with the same result, a linearly-polarized wave. Thanks for the refresher course.

Yes, got a good knife, but the wire is stranded, and corrosion will
get in between the buried strands. Considering ordering some solid
bare wire.

Of course, corrosion would grow all around solid wire, too... :-(

In reality, W1AW is strong enough that you should be able to hear it regularly even off the end of the dipole. And when conditions are moderately good, other stations also. Although I would still favor an inverted V for it's more omnidirectional pattern.

Like you, I am also in Michigan and I regularly pick up W1AW no matter what antenna I use. Since I can normally only listen to them at night, I typically listen to them on 40m, 80m or 160m depending on the conditions. I've also picked them up on 20m when I was home and that band was open.

Walter

I too used a HP slotted line alot when I was developing antennas in the 1950s. I never actually knew exactly what I was doing, and have forgotten most of what I once did with confidance. It is coincidantal that my primary reason for wanting to know the antenna impedance at 137 MHz is because I learned, a few months ago, that weather pictures could be produced from VHF satellite signals.
I reasoned that the pattern form two crossed dipoles spaced 1/4 wave apart and fed in phase could produce a bidirectional pattern with circular polarization. I thought that set of simple dipoles might be easy for me to build, if the antenna concept was compatible with the radiation from polar orbiting satellites, since they travel in a North-South path.

I am aware that the helix antennas are superior to the crossed array I'd like to build. Still, I am having fun learning about how these antennas work.

If I cant easily refine this slotted line, I may try building an impedance meter with the 4 coax lines, 1/8th wave long each. Perhaps the accuracy of the coax impedance meter will provide the accuracy missing from the slotted line method. Maybe the two 'devices' can compliment each other.

I was sure pleased with the way this slotted line worked last night when I fired it up. I am open to any criticism. This is only fun for me. But, since it seems to work so well, I thought there might be some interest in home made "Home Depot" quality (low cost) slotted lines for VHF.

Jerry

First... Congratulations.

You've had quite a few answers, but you didn't say which HF band(s)
you will be using.

It's been my experience on 160 through 40 that a dipole at 30 to 40
feet isn't very directional. As far as the East coast (I'm near
Midland MI) you should be able to work it with a 100 watts at night on
160 and 75. Day and early evenings on 40. The only problem with 40 at
night is the foreign broadcast.

I've worked California on 160 SSB with a dipole at 30 feet.
Not often, but I've done it. I've worked Europe on 160 CW.

No, my current station isn't using any thing at 30 feet except the
bottom of my back up vertical out in the shop, but it doesn't take a
big antenna or power to work 500 to 1000 miles on HF.

Remember too that the characteristics of these bands change quite a
bit throughout the sunspot cycle.

>
>Or should I go buy some bare solid copper wire?

Hi Bob,

Insulated will make a poor 60Hz safety ground (which you should
connect this ground to anyway). Insulated wire will make a perfectly
good RF ground (upwards to 5 orders of magnitude frequency shift makes
a considerable difference in what ground "means"). The pipe, on the
other hand, serves very little purpose. It is inadequate for a safety
ground, and useless for RF and maybe just suitable for providing a
mast base. It does give you a physical reference point - kinda like a
big solder lug.

Use up all your wire and enjoy - another 500 or 5000 feet won't bring
as much return as the first 500. For radials, try 10 X 50 feet, or 50
X 10 feet or something in between.

Thanks for all the reaponses. I apreciate them.

Let me give a little more info...

Rig is an ICOM IC751, I hava a MFJ-941D antenna tuner, and am contemplating putting up a WINDOM similar to the one described on buxcom.com. I would like to be able to hit the 20 and 40 meter bands. I'm not sure this is feasable, but this is where I'm at.

Thanks,
Doug

Nah, just practical and realistic.

This is just another "mad scientist" project. Technologically
feasible... well, just maybe... but totally devoid of common sense.

The amazing thing is how easily such projects find powerful backers at
corporate and even governmental level [insert cross-references to the
Dotcom Boom and BPL here].

509. 80 Metre mini loop

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-18 11:27:27 UTC
From: Michael <Michael-nospam@bigpond.net.au>
Message-ID: <z8tKc.6090$K53.2215@news-server.bigpond.net.au>
Source record: 92227

I recently saw a design for an 80M mini loop that was about 9 feet high and 16 feet long with ribbon feed as the matching capacitor.

Unfortunately I lost the design and can't seem to find it. I am not sure whether it came from the web or from a magazine.

Does anyone know of it?

Question -- is there a problem in using a safety ground as an rf
ground, too? If I connected 10x50-ft bare, buried radials to my little
pipe, and used it as a safety ground for the station, and also as a
ground to work an inverted "L" against, would that be a problem, or
should I have separate ground points?

Tnx to all who have replied so far...

The easiest way to get 20 and 40 m on one antenna, and ditch the tuner at
the same time, is to connect 20 and 40 m dipoles to the same feedpoint. You
just need some separation at the ends of the wire. I have a 17m dipole,
which is also the support for the 40m inverted V. I will try to come up with
some numbers for you.

The trunks of those puppies were the other half of the horizon. A kW
mobile rig in the trunk? No sweat! And with room left over for the
suitcases.

Then along came the Chrysler 300s. The PA State Police bought a flock
of "Police Special" 300s which they used to nail those big GM and
Mopar cruisers. The 300s surfed the PA Turnpike at 130-140 mph "CCS".
I was riding on the TPK in the sedate 1953 six-banger family Pontiac,
didn't see trooper coming, then *Whooosh!*, his pressure wave almost
blew us out of the lane.

Walter

I'm not bright enough to fully understand all this discussion. But, I wonder if the appropriate phasing of two circularly polarized waves, one RHCP and the other LHCP can result in a linearly polarized wave, not zero. I think I could build an antenna from two crossed dipoles spaced 1/4 wave apart that porduce either RHCP or LHCP radiation depending on how *one* of the dipoles is phased with respect to the other. Feed them in phase and get RHCP. Change the phase of either dipole 180 degrees and get LHCP. The "unchanged" dipole in both cases has the same polarization and phase.

If (theoretically) two of these antennas were superimposed on each other, only the phase of *one* dipole of each antenna needs to be 'reversed' to produce the 'reversed' (RH or LH) polarized wave. The other dipole of each antenna can be in phase with each other, so the sum is a linear wave.

What am I missing??

Jerry

Hi Bob,

The Safety ground as RF ground will be ONE radial equal in path to all copper it is connected to (your plumbing in other words, provided it is not plastic) - not bad, but not any great shakes. It was never designed nor installed to serve RF, just to keep 60Hz tamed around home, shop and garden.

You can build a separate Safety ground into your antenna ground system, but code demands you then connect both Safety grounds (to keep you, children, small animals, and your neighbors alive - this is not just a tedious bureaucratic exercise). The wire between them must be continuous (no splices). This also has the added advantage of cutting down on nasty noise problems called "ground loops" (the hum that refuses to go away or the strange operation of other electronics while you are transmitting).

A *physical* dipole is two halves of opposite polarity.
An *electrical* dipole has two major radiation lobes. A multi-
wavelength physical dipole has more than two major radiation
lobes and is therefore not electrically a "dipole". It's
splitting hairs but I try to differentiate between the two
meanings by including the proper adjective.

Gotta disagree here CW

The reason that this sort of thing is going on is that they are trying to lower those losses. The zapper may or may not be a practical device (I tend to think of it as quite impractical for most of the reasons already outlined) but it was brought about with the intention of *saving* lives. "Acceptable losses" hover very near zero, perp or innocent bystander. Otherwise a chase could be terminated very, very quickly.

Well, Jerry, your last statements is correct. Apparently you missed Roy's post, where he explained that two equal harmonically related RHCP and LHCP signals reduce to a linearly-polarized wave. I was out of my tree when I came up with the knee-jerk response of no signal. I knew better, but I spoke without having my brain in motion. Happens too often when one gets to my age.

don't worry about cecil, he just loves splitting hairs and using adjectives
that no one else would even think of applying. just give him a few more
messages and he'll be spouting on about some kind of reflection polymatrix
in his polypole or some such stuff... all when all the originator of the
thread wanted to know is if his dipole would work.

YES! it will work, stop reading this drivel and get on the air!

Doug,
I put some numbers into EZNEC, and came up with:

20 meter support dipole, 34.1 feet long at 40 feet.

40 meter inverted V hanging from 20 meter dipole, 66.7 feet total length,
with ends drooping down at 30 degrees.

SWR is less than 2:1 from 14.0 - 14.4, and 7.0 - 7.4.

Directivity is about 6db on 40m and 13 db on 20m. I think there would be
some advantage to not having the antennas in the same plane.

Hi Jerry,

I hink it's great that you can buy materials a Home Depot from which you can fabricate a slotted line having 50-ohm impedance. With smooth inner and outer conductors the inherent swr should be low enough for making acceptable measurements. In addition, if the teflon spacers are thin they should give only an insignificant discontinuity at 137 MHz.

You might still want to consider the quadrifilar helix. They are being used nearly exclusively for all frequencies on the NOAA polar-orbiting weather satellites. While at RCA in 1976 I performed an R&D project on the quad helix by investigating the radiation patterns and impedances on over 1000 different configuations. From the data obtained from my measurements, one configuration fit the requirements for the TIROS-N spacecrafts, which became NOAA spacecraft once in polar orbit. RCA built the entire series of TIROS spacecraft until RCA

was taken over by GE in 1986.

The report of my R&D investigation appears in Reflections II, and is also available for downloading from my web page at http://home.iag.net/~w2du. There is also a chapter in Reflections 1 and 2 that describes two configurations of the quad helix, one of which is that flying on the NOAA satellites;. The chapter number is 22, and is also available for downloading from my web page. That chapter gives the data for constructing the configuration flying on the NOAA satellites, which uses an infinite balun and self phasing of the helical elements. If you're not interested in constructing that particular configuration you can still feed the two helical elementss separately, using commercially made baluns and a 90ï¿½ phase shifter.

Jerry, the beautiful aspect of using the quad helix is that you don't have to point it toward the satellite. Just place it so the beam is vertical and at least 1/4wl above ground and it'll give you signal from horizon to horizon without aiming it.

Good luck with whatever configuration you use.

Walt

You have electronic power steering? When did they give up on
the vacuum/hydraulic systems?

Over the years I've seen quite a bit of this kind of thing. In my experience, it's not the brain child of a "mad scientist" at all, but a clever entrepreneur. He makes the idea sound plausible enough to get technically naive investors (which can easily include the government) to chip in, makes himself president and CEO of a company, and lives the good life as long as he can before the investors finally realize there won't be buckets of money at the end of the road and pull the plug. Although not required, quite a few of the ones I've known have a Ph.D., which impresses the investors. Some leave a trail of crashed companies behind them but manage to do it over and over, conning a new set of marks each time.

It doesn't take a very careful look at some of the "miracle" antenna proponents to identify a number of these operations at work right now.

I am planning on building a 15 meter and possibly a 20 meter vertical J antenna. Plans are for the bottom of the jay to be a position adjustable strap. Below the strap the two pieces will be connected together by short lengths of pipe welded to the vertival members. Tunning will be acomplished by movimg the shorting strap and telescoping the long side. Will the shorts below the strap have any significant electrical effects.

Jimmie

Well, be that as it may (and granted, didnt keep vehicle from resttarting), as two way tech for railroad, had complaint , and from MECHANICS about their TRUCK! Said when talked on radio, it would come to screeching halt, if they used their two way radio (160 mhz)! would key radio in front of the shop- no problem, thought they NUTS! Said, "Lets take for a test drive" And sure as all get out, ENGINE STALLED! what was interesting was that no problem when first installed the radio (*&$%*() truck then was around 20 years old, and that about 15 years ago)! Turns out that they replaced the old POINTS- Coil, Distributor with an Electronic ignition kit! Refitted it to the original, and no further probs (no info on what kind of caps to get rid of the rf for the original from the manufacturer !) -- But Roy is right-- after all, Couple fellow's (Gates and Allen) are college DROPOUTS, and they worth more bux than lotsa Ph D. s - combined! Only one PERSONALLY would trust (Ph D) is a fellow named T.J.Rodgers - founder of Cypress Semiconductors! Most of the the others are exactly what Roy describes !! Jim NN7K

> fine with a dipole.

Thanks Roy.

It now makes perfect sense to me that since CP can be generated with two linear antennas (crossed dipoles, phased appropriately), it must be true that one could make linear using two CP antennas - just as you reminded us.

Still - I have a nagging feeling that, taking advantage of the -3dB separation between CP and linear, there must be at least a small (3dB SNR) Shannon window in there that might be used to squeeze through some extra data. Likely not (yet) cost effective even it it does exist.

I appreciate all the responses.

Now - what shall I do with the $10,000 that I didn't spend on a patent ?

;-)

Jimmie:

Should work fine. I've built 10 meter J poles with similar technique. Make a "trombone" at the bottom of the antenna for impedance matching. electrically, the long vertical section is an "end fed half wave vertical" with a "quarter wave matching stub" formed by the J section and bottom of long part. You can make the radiator longer or shorter than a half wave and still match it.

Reminds me of the cartoon of the lineman whose job changed to running underground service - he said the hardest part was getting the holes deep enough to bury the power poles.
You got a lot of good advice already - I vote for bare copper - and use the ground rod and its ground clamp as a solderless lug to distribute the buried ground wires.

I see nothing surprising on LB's site.
The patterns are elevation patterns. The asymmetry results from the tilting
in the vertical plane.

The black plastic tube is the AM antenna, they often swivel around a
bit so you can adjust it's position for best reception. Sounds like
there is no FM antenna. You can buy an FM antenna easily, what you
are looking for is made of 300 ohm twinlead and is a dipole (actually
what is called a folded dipole) and can be found at Radio Shack,
sometimes at Target or Lowe's and I've even seen them at the 99-cent
store. The Radio Shack part number is 42-2385 and will set you back
about $5 (depending on your sales tax). Connect the antenna to the
screw terminals & hopefully that will solve the problem.

If you have extra speaker cable laying around I suggest you take about
6 or 7 feet of it and separate the wires on one end for about inches
then strip about 1/2 inch of insulation and connect one lead to each
screw terminal: at the other end separate the wires for about 38 - 40
inches and tack or tape them to the wall. You are looking for the
finished product to look like a 'T' with top being about 4-1/2 feet or
so. I've found little difference in performance between the homebrew
dipole antenna I've described and the commerical dipole and if you
have the wire laying around it lets you know fast and cheap if lack of
antenna is what the problem is.

Good luck,
Howard

Walter

I found pre-cut to 5 foot length two copper pipes at Home Depot. The large diameter pipe is 2.00 ID and the smaller is 0.875 OD. I made some ID and OD tapers about 3 inches long so they matched some N connectors. I dont actually know why I measure a reflection of 1/10 th of the incident voltage.

I must have been too sloppy with the construction somewhere. Still, I wasnt at all sure I could build something that would work so I wasnt sure how careful I'd have to be. I can probably learn where most of the discontinuities are. But, I can do everything I need to do with this "quick and dirty" slotted line.

As for the Helix for NOAA satellite reception, I agree that the helix is the best way to go for polar orbiting satellite pictures. I had heard alot of tales of difficulties about building QHAs and QFHs. I have a home made QHA that works pretty well. I dont understand how they work. But I like the way the work.

Right now I'm having fun trying to build a collapaable/foldable antenna for VHF polar orbiting weather satellite reception. The building of an antenna is the major reason for me being interested in WXSAT. I sure couldnt improve on the omni azimuth reception of a helix. But, what do you think about there being some worth in a crossed dipole that is oriented to look along the North-South? It is fairly easy/cheap to build and quite tolerant to errors in dipole element length.

I am sure that you are vastly more knowledgeable about the radiation pattern and coverage of the Cross than I am. It seems to provide good signals toward North and South with good RHCP within about 90 degrees both North and South, without "aiming". I oriented the antenna so its nulls are East and West at low angles. I reasoned that satellites traversing those low angle toward the East or West would be viewable for only minimal times when only polar orbiting satellites are considered. I tried orienting the antenna so the null occurred at zenith, so the East-West sensitivity would improve, but I cant fill the overhead nulls.

I'm getting carried away with a discussion that probably interests no one.

Jerry

I built one for 10 out of 1/2 inch copper pipe. admittedly, this isn't the
best material (pipe is too flimsy for high wind conditions without bracing).

I would suggest you check the following site for building a J antenna:

http://www.cebik.com/jp1.html

that site has an entire treatus on how to build one from scratch
(including formulas).

I would, at the very least, recommend 1.5" or 2" copper pipe for the
J-portion, followed by 1" pipe for the next section and completed by .5"
pipe for the last section (all parts are available at home depot for
minimal cost).

Be aware thopugh, the increased diameter of the lower sections will have a
very large effect on where your best match will ocurr..

Second that! My 66 Fairlane with a 289 V8 got 17-21MPG. My 68
factory-special GTO would just lift the left front tire off the ground
coming off the line, and charge past 120MPH, but got 12 MPG. My buddy's
1972 340 Duster was slower than the Fairlane and barely got 12 MPG. The 72
made less nitrious oxide than the goat, which was good for LA smog, but made
more half-burned hydrocarbons that the rest of the country didn't need.

Patt,
Now you know why they 'gave' it to you, huh? Before spending
any money on an antenna, try attaching ~any~ length of wire to the
antenna terminals. Hear anything across the FM band? If not,
then the problem is probably in the receiver and not the lack of an
antenna. Do you think the receiver is worth repairing?

You had 8" floppies? Let me tell you, when I was young we didn't have any such newfangled nonsense. No, sir, we thought ourselves lucky to have punch cards. AND we punched them by hand -- none of these fancy keypunch machines for us (grumble, grumble).

I still do have a box of punch cards somewhere, containing:

1. A simulator written in 3600 Compass assembler, for a hypothetical machine we had to design. (The 3600 assembly was itself run on an emulator running on a CDC 6600.)
2. An assembler we wrote for our hypothetical processor.
3. A program written in our hypothetical assembly language, to be assembled by our assembler and run on our emulated processor. I don't remember what it did, probably sieve of Eratosthenes or something.

I'm not sure if the cards are in order any more though :-)

Regards,
Allen

Hi Allen,

When I mentioned the 8" disks I was referring to my own personal computer era.
While working at RCA in the early 70s I had others write the programs I needed,
and they punched the cards for me, so I was there then also, but not the extent
you were. Thus you were way ahead of me in computer use.

Wrote and punched my first computer program in BELL on punched cards for an
IBM-650. The computer filled, as I remember, with dual triodes, was huge,
but the air-conditioning to keep it cool was bigger. The only permanent
memory was a magnetic drum, used for program and data. (Remember head crashes?)
It used the bi-quinary number system (like an abacus?).

Remember when there was a tube checker in every grocery store?

"Bob Miller" <bxmillerNoSpam@texas.net> wrote

For my general station ground, I have a copper pipe that goes down
about one foot -- then hits rock or limestone or whatever.

I'd like to enhance the pipe with a few buried radials. I happen to
have a 500' roll of 14-guage stranded *insulated* copper wire. Will
the insulation keep the wire from becoming "one with the dirt"?

Or should I go buy some bare solid copper wire?
---
and then Bob added:

Question -- is there a problem in using a safety ground as an rf
ground, too? If I connected 10x50-ft bare, buried radials to my little
pipe, and used it as a safety ground for the station, and also as a
ground to work an inverted "L" against, would that be a problem, or
should I have separate ground points?
--

Hi Bob, can you be more clear on what you meant by "general station ground"?

Since you're in thunderstorm country it could be you mean a lightning
protection ground. But you also mention safety ground and RF ground so it
appears you have multiple requirements here.

Conductor choices vary according to the function of the system so it is
difficult to generalize about stranded v. solid wire until you can be more
specific in your requirements. In some cases neither kind of wire is
appropriate, with wide/heavy gage copper strap being the best choice.

However many purposes your ground system fulfills, and from however many
places it connects to ground rods, one standard always applies: you must
always bond all of your earth-references (ground rods) to your station
equipment AND the main entrance ground of utility wires coming into your
home. Preferably that station single point ground and the Utility single
point ground are the same place. Unfortunately few of us are so lucky as to
be able to locate our station right at the main Utility service entrance.
When the two are far apart that creates problems. With a lot of help from
this group, and professional engineer review, I completed a station
grounding and lightning protection system that accounted for those problems.
The complete site construction plans are listed at:
http://members.cox.net/pc-usa/station/grounding.htm

Hope this helps,

Bob, K5QWG wrote:
"Or should I go buy some bare solid copper wire?"

Depends on frequency. As a path for electricity, the earth is like a leaky capacitor or a good capacitor in parallel with a resistance.

Terman says on page 807 of his 1955 edition:
"At broadcast (550-1600 KHz) and lower frequencies the ratio of capacitive reactance of the earth to the earth resitivity (sigma reciprocal=1/conductivity) is considerably greater than unity, so to a first approximation the earth can be considered as purely resistive.----Conversely at frequencies of the order of 10 MHz and greater, the impedance represented by ground (not sea water) is primarily capacitive, and ground-wave attenuation at a given physical distance is determined by the factor of frequency divided by the dielectric constant plus 1."

So for low frequencies use bare wire. For high frequencies, you won`t notice insulation on your radials, electrically.

Best regards, Richard Harrison, KB5WZI

The DIRECTV and Dish Network antennas receive in the 11 to 12GHZ range
and someone (very) clever could probably mod the LNB for 10GHz amateur
use. These 18" reflectors start getting useful at about 2.4GHZ on up,
below that I would agree with Jim.

The last we heard, the antenna and it's Father had been nominated for the Nobel Peace Prize, and were currently touring in Africa, where the antenna was being investigated for it's potential use in curing aids and feeding the hungry. It's a shame, but we may never see this wunderantenna stateside again. It will probably be cannonized by it's Italian EH brothers and only available through special internet offers. If we're lucky.

Mr. Vincent appears, based on his public statements, to be planning a roll out coinciding with the August ARRL New England Boxboro convention (August 14 I believe). I could provide a link, but I just checked it and it is down.

Just so it is known accurately, there is(are) no patent(s) on Mr. Vincent's antennas.

I suspect he will have some high quality data to show --I am not convinced, based upon his public comments, that he has become sufficiently aware of the state of the art of monopoles, nor that he is fully schooled in the prior art of distributed loading. This is my opinion. Of course, he may have sought such knowledge since 4 June, which would be most admirable.

For example, one of the principle themes in his comments is that 'my designs require a fraction of the loading of conventional monopoles'. One thus is led to believe--again, my opinion- that the reactance has disappeared in some way. In fact, if you compare with mid-loaded designs of straight short monopoles, there is less of a coil load--but this is only for THAT coil: he has used a helix, instead of a straight wire, upon which to place that loading coil. There is STILL AS MUCH IF NOT MORE loading with such a design; its just not forced onto a single coil. THERE IS STILL OHMIC LOSS in such designs--it hasn't gone away. Ohmic loss means a departure from 'high efficiency'. I suspect he has no data on efficiency, but has tried to infer it instead. It would be refreshing to see that this is not the case.

He also claims 'wide and excellent bandwidth'. In fact, better bandwith is an intrinsic property of mid-section coil loading, as shown by R.C.Hansen many years ago, and well known to many monopole designers. However, the 'excellent

and wide' bandwidth is only a few percent at best: this is NOT a monopole that works over decades of frequency, nor even many different ham bands in a controlled way.

There are many past examples of Mr. Vincent's comments that indicate, in my opinion, that what he has is not novel. Again: my opinion. This is from someone who is skilled in the art.

After the roll-out, if Mr. Vincent has not been able to come up the learning curve sufficiently, I will publicly disclose additional factual corrections and comments regarding the DLM antenna, and prior art. Of course, this is not a reflection of Mr. Vincent nor his efforts, but a friendly and technical insight into what's possible and a glimpse of what's already been done.

In defense of Mr. Vincent, I am strongly of the opinion that what he has done is not 'snake oil', and it is deleterious to ham radio for some to be so verbal and public in this characterization. However, the question is whether the technology does something new and in some novel way. That is a valid question to ask and I suspect will be answered, over time, in the negative--again, my opinion.

73, Chip N1IR

That depends on a bunch of factors you didn't mention. A 1/4 wave CB antenna is about 11 feet long IIRC. More important, it needs a ground plane with the same radius. Most perforce shorten the antenna using coils, at the expense of efficiency and pattern shape, and get by without an optimum ground plane but both transmission and reception suffer - how much depends on the vehicle, the antenna(s) and where you mount it/them. A pair of antenna may yield a pattern favoring the road ahead and behind depending on seperation. That's why big rigs use them. I had a cross-bed tool box with one 6' "Firestick" mounted in it's center that worked as well or better than anthing else I tried.

Of course 2 meters is the better solution.

Just got through building a 10 M version of a J. Think a 20M version will be
a lot longer than I had invisioned. While I knew the numbers before I
started, the reality of how big it would be did not sink in until
construction of the 10M antenna. I still want the 20 M vertical. Obviously
some redesign is in order. Possibly I will constuct the J out of feedline
and run it horizontally to the shack.

Everything depends on your news server. When you post a message it is cued for posting with all the other current postings. Depending on how busy the server is, it may not be able to process new postings until it expires a bunch of old ones, to make space. Then it processes latest postings and sends it's information off to other servers for posting. The other servers have the same thing to deal with. If they are busy they may even refuse a packet of postings and your server would have to try again later.

My news server is somewhat local to me and I see my postings within a few seconds of posting. But there are some news servers where I won't be able to see my post show up for 6 or 7 hours. Google groups is like this.

I just take it on faith that my posting got out. Even when I see it on my news server, I have no idea when it will reach any of the other servers.

574. Distance between outer ends of buried radials

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-20 15:12:46 UTC
From: sjbeyers@trianglenet.net
Message-ID: <72befaab.0407200712.64b92d38@posting.google.com>
Source record: 92145

I remember reading somewhere that one way to determine the optimum number of buried radials for a vertical antenna is to use a specific value for the distance between the outer ends. (I'm not sure if this is the straight-line distance, or the length of a chord, but there wouldn't be much difference.) But I can't remember the value. Something like .05 wavelength rings a bell, but I'm not sure. Does anyone know what the value is and where I might have read it?

Thanks -

Steve W9HJW

That's what I always thought, but according to one of the links you provided
http://www.signalengineering.com/ultimate/mobile_antennas.html
it's done to even out the skew in the omnidirectional pattern caused by the
asymmetric vehicle ground plane.
For the 18-wheelers with side mirror mounted antennas it might also help to
eliminate the shielding effect of the large trailer body if only one antenna
was used.

A real simple measurement would be to walk a circle around the truck with a
field strength meter and see what you've got.

But for anything else than an 18 wheeler I think it'd be a total waste. But
then again with CBers it's not just about how you sound but about how you
look !

Thanks for the in-depth answer, Chip. I'll be waiting for the
convention. This and your other post a while back gives me an idea of
what to expect. Perhaps the antenna does indeed work in it's fashion,
and is the victim of the "hype machine". It will be interesting to see
how closely it resembles what was described in your earlier post.

580. Variable diameter antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-20 16:57:42 UTC
From: Mike Coslo <mjc5remove@psu.edu>
Message-ID: <40FD4F06.6030100@psu.edu>
Source record: 92151

Reading through the 20 meter J-Pole thread got me to thinking.

<<<<possible idiot question alert!>>>>

If a person was to design an antenna that had variable diameters, such as a telescoping pole, or a thin whip antenna on top of a thicker pipe as talked about in the J Pole, what effect would this have on the BW of the antenna. Of course, (I think) it would be less than if the entire antenna was made of one thick length. But I could be way off here. And would it be calculable?

And could variable diameter be of practical use in antenna design?

Hi J

Many eons ago, almost more than I care to remember, I was using SIX 102 inch whips on my rig. They were actually two sets of three whips cophased together. Using three whips in a small 3 inch triangular pattern allowed the whips to be shortened so they would not clip the occasional low bridge. The purpose of cophasing was obvious, it was to get more front and rear directional along the roadway.

Whether you use a single whip on each side, twin whips or triple whips your spacing between the two units must be far enough apart for it to make any difference. Or, in our case, that big box behind us was like a shield to radio signals.

FWIW, a 1/4 wave magmount sitting on top of the trailer was often more effective in and around cities, where a 1/2 wave magmount was more effective on the road than the cophased whips. That is, until you crossed under a bridge and wiped them off the trailer.

Unless you can get those whips at least 8 feet apart, it's not really worth messing with!

>And could variable diameter be of practical use in antenna design?

Tapered elements are common used in HF. They tend to load the antenna a bit, thus shortening it. Some BW increase results as well.

At the other extreme, a continuously inverse- tapered antenna is quite broad in bandwidth. Thus the Oliver Lodge, or 'bowtie' antenna, from 1897.

Old, old stuff.

Dear Bob:
Thanks for passing on the information.

Prof. Kraus was and is my mentor in grad. school. His kindness and caring for others, his willingness to work hard, and his generosity are also included in his legacy. He spoke softly, but in such a way that you wanted to run to meet his expectations.
Analogously to the custom in mathematics, I tell my worthy students that their Kraus number is 2 and that their students will be 3.
In addition to my father and my geology professor (James Zumberg), I have tried to emulate Prof. Kraus all of my life. They were the personification of the non-egotistical, helping genius. Too rare in any age.
Prof. Kraus was also a pioneer in radio astronomy producing, as I recall, the second atlas after Grote Reeber, who I once worked near. The two men were fast friends.
Let us all rejoice in such a long and productive life. If we can but approach a fraction, we will have lived well.

'till we meet again, 73 Mac N8TT

590. Re: Circularly Polarized for LPFM

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-20 20:04:48 UTC
From: "J. McLaughlin" <JCM@Power-Net.Net>
Message-ID: <10fqum6j4u9gje6@corp.supernews.com>
Source record: 92161

My antenna question only stimulated Mr. Fry, a continuing, constructive contributor to these proceedings. Here are some of the conclusions from our correspondence and our modeling:
1 "Ring-stub" is an appropriate name for this antenna and was found to be used by others.
2 Contributions to vertically and horizontally polarized far-field signals is proportional to the diameter of the ring (for H) and height of the stub (for V). [The first antenna that I looked at had disproportionally tall stubs.]
3 At 94 MHz, it appears that a diameter of something like 300 mm and a stub of about 230 mm about balances V and H. An optimum set of dimensions was not found. Too many parameters exist to allow quick convergence.
4 Radiation from the customary Gamma match used with this antenna significantly distorts the FS pattern. Placing the "arm" directly under one branch of the ring reduces the pattern distortion.
5 This type of antenna is usually mounted off to the side of a tower. Manufactures often speak of towers no larger that 3 or 4 inches in diameter. With reasonable offset distances from a 12 inch diameter metal pole (the tower that is likely to be used), the driving impedance changes dramatically.

This hitherto unknown (to me) antenna seems resistive to rational design and is a candidate for heuristic design - if at all. Once again, I ask if anyone has dimensions of a well working example of this antenna.

Mind, for LPFM stations, the FCC is concerned with the average (or rms) antenna gain. That is little changed with large changes in the shape of the pattern. The University wishes to know where the gain is going. Remember the first law of antennas: all antennas work. The second law is: some antennas work better in certain directions than other antennas.

Hi Jan,

Indeed it is a nice chip from the Cadillac of linear designers.
However, what distinguishes it as being a good choice for a small
"magnetic" hf receiving loop?

The loop itself may restrict the input BW, but it takes more than that
to build a receiver. Consider, there are many other Op Amps that
deliver as much gain at HF and are purposefully designed for just
that.

To put some perspective to this; what about the AD8099 makes it better
than a diode detector and the classic ï¿½A-741?

> other antennas.

True, the FCC is concerned only with the RMS gain of an "omni" FM broadcast antenna, no matter how bizarre its real patterns. The antenna OEM publishes his antenna gains based on perfectly omni patterns in the horizontal plane, and those values must be used when determining the ERP of an FM station -- no matter if the true patterns have multiple nulls in the horizontal plane that may be only 10 or 15% of that gain. The problem is in knowing what those true patterns are from an installed antenna.

Operating and installation details such as the tower width used, tower construction details, FM frequency, antenna azimuth/elevation/offset on the tower, presence and location of conduits and transmission lines and other metallic structure in and near the antenna aperture, tower guys etc all can have a significant, often unpredictable affect on the final radiation patterns from the installed antenna.

The safest way to know what the patterns of the installed antenna are likely to be is to have them measured on the OEM's test range, using a replica of the tower or pole on which the antenna will be installed including all the "stuff" in and near the antenna aperture, and the pick a mounting arrangement that produces the most omni patterns. For c-pol (and v-pol only) antennas, that may require adding vertical parasitics near each element to fill in the natural v-pol null caused by the antenna supporting structure, which is essentially vertical. (N.B. The patterns from FM transmit antennas mounted on towers of large cross-section are difficult to impossible to fully optimize using parasitics.)

I kinda wondered if you realized a 20m "J" would be about 49' or 50'
of pipe. You need to put up a picture if you get the thing built :-)

If you construct it horizontally out of feedline it'd be like the end
fed "zepp" trailing antennas they used to hang out of air ships.

Steve, W9HJW wrote:
"Something like .05 wavelength (between ends of buried radials) rings a bell, but I`m not sure."

That would depend on the length and number of radials. But, the .05 number may be significant in the case of 120 radials. 120 radials is an FCC standard. Spacing is 3-degrees.

In a right triangle, the side opposite an angle is equal to the tanget times the adjacent side length. For a 3-degree angle, difference between the adjacent side and hypotenuse lengths is insignificant.

The tangent of 3-degrees is .05. The distance between radials spaced by 3-degrees is therefore very nearly .05 times the length of the radial. That`s my guess as to the source of Steve`s .05 number.

Best regards, Richard Harrison, KB5WZI

I think Mark Keith`s testimony is accurate. Signal grabbing depends on the area enclosed by the loop.

Small loops discriminate against noise due to their directional response. So, if the actual antenna is the shield or the contained conductor makes little difference except we have Terman`s testimony that the shield can equalize electrostatic response and in some cases reduce noise.

What effect would it cause if you ran a wire around the perimeter of the
radials - connecting them together ?
And I guess you could do it again at the half-way point so it resembles a
spider-web.
like a big fence just underground.... could you then reduce the length of
the radials??
I may just try this on a manageabe scale - say 10 meters

Hi Hal,

You would then think of the problem in terms of how far must ground
current traverse through soil to find a conductor? This is a loose
analogy because the current traveling through any patch of ground is
infinitesimal. Rather, it is the efficiency by which the radials
shield the antenna from the "bulk" of ground beneath it. Hence,
thinking of it in terms of 3D and proximity yields a better conceptual
model - further, it allows you to understand why elevated verticals
with fewer radials have an equal capacity for "getting out," or so
reports offer.

It also works, roughly, for shorter radials.

Jerry Sevick, W2FMI, published data on the effects of shorter radials on feedpoint impedance, and came to the conclusion that if you use shorter radials, there is little advantage in using very large numbers. If you re-plot Sevick's data, it turns out that, for a given length of radial, you only need about enough to ensure that the ends are about 0.05 wavelengths apart. Adding more radials of the same length will bring little further reduction in feedpoint impedance.

However, this is a "soft" limit, so others may interpret the same data to say that the limiting tip-to-tip spacing is different, even as little as 0.02 wavelengths.

The "tip-to-tip rule" is a useful guideline, but it isn't helpful to argue over the detail, because feed impedance isn't the only important criterion. Longer radials will also reduce losses due to ground reflection, and improve your low-angle signal in particular... but in order to make a difference at very low angles, the radials need to be very long indeed.

All the "tip-to-tip rule" is saying is: if the radials are as long as you can make them, and you already used enough to make the tips 0.05...0.02 wl apart, then you've done all you can. Go look for something else to improve.

Hello, Dick and the group,

Have a look at www.w4mq.com , Stan Schretters website. He developed and setup tis whole system. Currently, there are some 5 or 6 stations accessible over the internet. Some are closed club systems, some are open for public (ham only) use worldwide. Including stations in the US (MA,VA,GA,CA,FL), VK3, EA8, there might be more of them for private use by their owners.

You can use this software to remotely control your Kenwood TS2000, Tuner, Amp and Beam over Internet connection, and due to the small amount of bandwith, even with dialup access (but not recommended).

www.w7dxx.com
www.daves-portal.com
http://tnsley.tripod.com/w6wtg/
http://www.olt.net/hams/

These are some additional links for you to check out, how those guys accomplished to put their stations on the net.

Hope to meet you on the air from one of the remotes.
I am frequently QRV in PSK and SSB from one of the Internet Remote Bases on 20m, mostly around 0400z.

Hello,

Steppir has the tunable yagi antennas:

http://www.steppir.com/products/prod-3el.htm

In those, the yagi element lengths are changed according to each band. I am thinking of doing a homebrew antenna based on the same principle. My antenna would be a three element quad. It would have two booms, both having three 4m long horizontal glasfibre pipes. Thus, the boom with the pipes would look like a 3-el yagi. The upper boom would be attached to the tower and the lower boom would be hanging from the antenna wires of the three elements. The lower boom would go up and down depending on the band and the total loop length. The three motors would be located on the upper boom. The wire would propably be a steel wire. With 4m pipes the distance of the upper and lower boom would vary from 1m (4m+1m+4m+1m=10m band) to 6m (4m+6m+4m+6m=20m band). On the end of each pipe there would be a small wheel to assist the sliding of the wire.

The whole thing would be microprocessor controlled (8051, Atmel AVR etc). At the beginning it would have to be tuned to each band in order to extract the correct loop lengths. The lengths would be stored to the flash memory of the microprocessor.

What do you think? The element spacing would be fixed, is that ok?

> metal pole (the tower that is likely to be used), the driving
> impedance changes dramatically.

The input impedance of any/all sidemount antennas (ring-stub or otherwise) is affected by the electrical environment in which they operate. A common input spec for a sidemount FM transmit antenna without on-site matching is ~1.5:1 VSWR. FM transmit antennas with input VSWRs greater than about 1.15:1 across the 200kHz bandwidth of the channel can noticeably reduce stereo and SCA performance.

A transformer can be installed at the junction of the antenna input and main transmission line to provide a way to optimize the match after antenna system installation. But this takes some rather good test equipment, not just the typical in-line wattmeter (Bird, etc) or the VSWR meter in the transmitter.

Note that installing and adjusting an input matching transformer on an FM transmit antenna does not affect antenna radiation patterns. Final patterns are a function of the antenna design, and the electrical environment around the antenna (within several wavelengths).

Richard, thanks for the reply.
The AD8099 is an ultralow distortion low noise high speed opamp.
You need all three: ultra low distroriton, low noise and high speed/BW.
I dont know an other single chip opamp with these very good specs.
If someone knows a better one, please let me know.

Of course it only makes the loop antenna, not the receiver.

IEEE has a short professional biography of Dr. John D. Kraus W8JK
at: http://www.ieee.org/organizations/history_center/legacies/kraus.html

Here is a copy of a newspaper article from 10 years ago that
describes some of Dr. Kraus' accomplishments specific to radio
astronomy and SETI, especially at the Big Ear Radio Observatory.
http://www.bigear.org/kraus.htm

I recommend that *all* Amateurs that they read Dr. Kraus' book
'Big Ear' (now available as 'Big Ear Two'). It's largely an
autobiography, but not of the boring "I did this, then I did that" type.
It's an interesting tour through radio and technology in the
period paralleling Dr. Kraus' life in the 20th Century, from his
viewpoint in story-telling style. Here's a short review and some
information about the 'Big Ear Two' book:
http://patriot.net/~jlazio/essays/review4.html
http://www.cqbooks.com/bigear2.htm

I also liked his book 'Our Cosmic Universe', which is a non-technical
description of astronomy (of all types) in the 20th Century.

That would enable and enhance current travel in circles around the antenna base of no value to the radiated signal but a loss sink for precious power. Ed Laport in "Radio Antenna Engineering" warns against this "hysteresis current" product in several places and refers to it as a "former practice". Ed had the benefit of working with Brown, Lewis, and Epstein at RCA and used their data liberaly in his book.

Ian White, G3SEK wrote:
"It also works, roughly for shorter radials."

Yes. .05 times the length along radials spaced at 3-degrees gives the approximate distance distance between them at any point. It doesn`t have to be between tips, just the same distance from the tower on both adjacent radials.

Ed Laport says more and longer radials is better, but there is a point of diminishing returns which occurs at 1/2-wavelength.

I`ve seen other reports that radial wire is better used when cut into more and shorter radials.

The FCC`s 120 radials of 1/4-wavelength has been efficient for medium waves in thousands of instances in all types of soil. It`s overkill in highly conductive soil, but regulations must be somewhat uniform for satisfactory enforcement. FCC`s rule is based on B,L,& E`s research. As I recall, B, L, & E worked at 3 MHz.

Best regards, Richard Harrison, KB5WZI

Doug,
If you go with the 20/40, you have to trim the 40 m first, because it has
more effect on the 20 than the 20 does on the 40.

John Kraus was also my mentor through his great book, "Antennas", Ed 1. John was also a close friend of another of my mentors, and colleague, Dr. George H. Brown. John credited Brown for originating the concept of increasing antenna gain through close spacing of the elements, which resulted in the two-element W8JK beam. Brown was ridiculed for suggesting such blasphemy, even by the US Patent Office in rejecting his patent application. But it was JK who realized its significance and applied it.

It is sad and unfortunate that such a great person has to leave us. Thus endeth his great contributions.

Hi OM,

Certainly sounds ambitious. As for fixed spacing, you would be sacrificing an optimal separation, but that would be the least of your problems as you describe the design.

>With 4m pipes the
>distance of the upper and lower boom would vary from 1m (4m+1m+4m+1m=10m
>band) to 6m (4m+6m+4m+6m=20m band).

This describes (I presume) three equal sized elements for either band (and I would further presume, for bands in between too). What makes one a director, one a fed element, or one a reflector? If they vary independently to maintain those relationships; then being fixed top and bottom by another boom may offer some problem. Then again, maybe not, it isn't that much different and the two booms would only pull slightly together.

As for the rectangular shape for the 10M band, that is a very different feed Z than the more square shaped on at 20M.

You are going to need modeling to be able to find the separations of the elements that work over these frequencies as well as to find the feed point Zs. The rest are simply mechanics, which unfortunately may be the easy part.

Hi Jan,

Yes, the AD8099 has all of these qualities, but it is arguable they are "necessary." There have been any number of chips from Analog Devices for years that have had the best distortion, noise, speed, etc. This chip is simply the newest in that line.

There is a world of design to make any of these chips work for your purpose, but you have not actually specified that purpose. In the world of engineering this chip selection is called "a solution in search of a problem."

Is it going to be the pre-amp to a receiver? Is it going to be the receiver? Will it be gain controlled? What gain will it need? What feedback do you plan to use? Do you know how much noise it will see? How much out-of-band voltage will it see? The more important considerations have been undiscussed: CMRR is one that can blind-side you (or the worse PSRR).

In short, could a simple low noise transistor replace it?

Richard,
for a shortwave broadband receiving antenna (my purpose) you
need even better specs that this chip gives you. I don't know of a
better (available) single chip amplifier for a broadband "magnetic"
loop. Of course when you are able to design your own chip .....

That's why I have designed a 6 transistor broadband amplifier
for the broadband "magnetic" loop. I don't want to bother this
group with all the design aspect. This amplifier is not that difficult
to build, but it takes more time to build than the single chip
amplifier. So this chip is a simpler alternative for someone who
want to try "magnetic" loops. That's all.

The 6 transistor amplifier however gives much better results:

We should always be careful in applying commercial broadcast standards to ham radio. For a broadcaster, the gain of a few percent in radiated field represents a measurable increase in the audience size, hence a significant increase in annual revenue, so it's worth a considerable one-time cost. For most amateurs, it represents only a fraction of a dB of signal strength, so isn't worthwhile.

This question may be slightly offtopic but I figured I would post to the group that knows antennas best. I have 2 TV antennas, one VHF and one UHF, that I would like to combine to use a single coax feed. The specs on a suitable joiner state it has .5dB insertion loss with 30dB rejection between ports. The specs on a typical splitter are 3.5dB loss and only 20dB between ports. The question I have is why would anyone ever use a splitter instead of a joiner? Are there any applications where you couldn't use a joiner instead of a splitter? Thank you.

> with this?

Yes, particularly on 80 and 40 meters.

> Specifically, I'd like to be able to monitor the W1AW bulletins,
> code runs etc.

You will have no problem. W1AW runs full power into some pretty good
antennas.

With the antenna only 40 feet up (a little over a quarter wave on 40
and eighth wave on 80) the pattern will not have sharp nulls. You'll
hear plenty.

Just put it up and enjoy it.

They are different things. A joiner separates (or combines) the UHF from the VHF with filters. That is why there is so little loss. If you used one to feed two TVs, one of the TVs would get the UHF, the other the VHF. The splitter is more or less frequency independent, and feeds half the power to each output.

Yes. I remember reading John Kraus` account of the situation. As I recall, the IRE rejected George Brown`s findings and would not publish his paper. Kraus figuered the IRE wouldn`t publish a similar paper from him either. So he waited his time until he had a related paper to publish and then Kraus attached Brown`s work. It sailed through the reviewers and was published.

Source record: 92105

Each individual radial is obviously a single-wire transmission line buried in a lossy medium.

As with all lines, it has Zo and attenuation, and when length is being considered its propagation velocity is of great importance.

Due to the very high permittivity of water (80) and the water content of all soils, rocks even, the velocity factor VF along a buried wire is much smaller than the free space value. Even when just resting on a slightly damp soil surface the VF roughly falls to 0.5 which can be easily checked with a hand-held antenna analyser. A 1/8-wavelength of wire behaves as a 1/4-wavelength when on the soil surface but with a poor Q.

Soil permittivity K is tabled alongside soil resistivity (conductivity). Velocity in a transmission line is proportional to 1/Sqrt(K). So a typical value of K of 14 results in a velocity factor of 1/Sqrt(14) = 0.267 i.e., only 27 percent of the free space velocity.

Attenuation along a buried wire is quite high. Typically it is 8 to 10 dB per 1/4 wavelength at its own velocity depending on soil composition.

Therefore, not only is a buried radial VERY much shorter than its free-space value, there's not a lot of current flowing in it near its end - and if there's little current flowing in it, it may just as well not be there.

There is not much point in increasing length of radials beyond that when input impedance of the line is already Zo.

The moral is - if you have any wire remaining after laying some short radials then don't use it to increase their length - increase their number!

For performance of radials in quantitative terms there are 4 programs which may be of interest at my website.

EARTHRES analyses DC and VLF performance of ground rods, plates, etc., and of a system of ground radials of any number and length.

RADIOETH demonstrates behaviour versus length at VLF to HF of a single radial wire.

ENDFEED and TANT136 integrate the calculations of the first two programs by incorporating them in working models of inverted-L and T-antennas respectively.

Remember the accuracy of performance predictions depends on how accurate you know the soil resistivity and permittivity in the vicinity of your antenna.

The specs on combiners are always tough to figure out. What most people think of as 'insertion loss' is actually division loss. The1 to 2 splitter with 3.5 dB insertion loss probably claims 3 dB of division loss --and 0.5 dB dissipative loss.

Its very unlikely its 3.5 dB of dissipative insertion loss. Even cheap power dividers--which are split delay networks with chip resistors--tend to be better than 3 .5 dB of dissipative loss, when they work.

640. TGM MQ 36SR deserves a try ?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-22 11:05:00 UTC
From: Thierry <"Answer direct via http">
Message-ID: <40ff9f5c$1@news.vo.lu>
Source record: 92111

Hi,

I would like to buy a moderate size (as well at a moderate price) a multiband beam like a TGM MQ 36SR ($550, E811)

It gain is around 6 dBd, quite interesting with a F/B ratio quite interesting too.

Question.
This antenna being sold for over 8 years now (maybe more), if was probably used under various climate and working conditions.
Living in a temperate climate (LX and ON, with a lot of rain and snow) I would like to know if this is a good investment :
- if you experiment hardware problems
- servicing problems, etc,
- and if you have to make a new order, if you will order the same model, or never more ?

Thanks in advance

641. Antenna height vs roof height

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-22 11:25:39 UTC
From: Thierry <"Answer direct via http">
Message-ID: <40ffa433$1@news.vo.lu>
Source record: 92112

Hi,

A question about the installtion of a short beam on a roof/chimney.

My house is built on top of Meuse valley, 250m high, surrounded with open field (and much wind, hi).

The roof top is at about 6m high. There is a small chimney 2m high. This part of the house contain only the garage and in front (garden side), the small boiler.
Here is the picture,
http://www.astrosurf.com/lombry/Radio/ant-longfil15m-eo3.jpg

I want to work mainly on bands of 20, 17 and 15m (and much less on 12 and 10, say 10% of time). So the antenna 'd be placed at 10m high and i can reach this height : I could place a small mast 3m high on the chimney attached with simple aluminium straps and screws, so the antenna will be at about 10m high. I hope it will be away from any interference with the boiler ignition system.

Question:
Is it important to place the beam much higher than the chimney (say at worst 10m higher that any building) or the main problem is the height over the ground of the house (I suspect the second) ?

At last, any experience with a TGM MQ 36SR at various heights is welcome (I read the eham reviews but there is not much accurate opinion in this regard, excepting that everybody does not share its good performances...)

PS. My alternative should be to place the antenna 5 m high over ground at the end of the garden (60m away), simply attached to the supporting wood wall of a small cottage ... :-(

I found the reference - it's in John Devolere's Low-Band DXing, 1999
edition, page 9-13. I recommends .015 wavelength between radial ends
for 1-4 wavelenth radials.

Thierry,
With a few precautions, I'd place the antenna on the chimney. The primary precaution is to make sure the chimney is constructed so as to be able to support the antenna and mast! Chimneys are not usually built to withstand very much stress from the sides, the antenna and mast will place higher than usual stress on the chimney because of they're wind resistance.
The effective height above ground will be slightly lower than the antenna's actual height because of the proximity to the structure. No idea what that effective height might be, and probably not a huge amount of difference from the actual height above ground. In general, the more height, the better the performance. A meter or two won't make ~that~ much difference either way, though.
I've no experience with your particular antenna so am no help there.
Good luck...
'Doc

646. Why does my antenna need grounding?

I just bought a new Sangean PRD2 radio. It has provision for an external antenna which I hooked up. There is also a terminal for a ground wire. Is it neccessary?

Thierry,
I would go for the chimney. I presently have a 19 element 432 antenna and an HD73 rotor on the chimney with a 10 foot Al. mast. Just make sure the chimney is strong enough. I put the mast on one of the inside corners of the chimney, and the end of the mast is actually supported on the roof. This takes the dead weight off the chimney mounts, and makes for a longer moment arm. Also, put it on the more upwind side.

Osama Bin Ladin was found hanged by two CNN journalists early Wedensday
evening. As evidence they took several photos, some of which i have included
here. As yet, this information has not hit the headlines due to Bush wanting
confirmation of his identity but the journalists have released some early
photos over the internet..

Thierry (http://astrosurf.com/lombry/post.htm):

in re: your proposed chimney-mounted antenna.

Be advised that carbon build-up from furnace, boiler, or fireplace operation is extremely conductive and can soon form a static connection between an antenna and the chimney-flue opening, and across various elements of the antenna also. This is to be avoided. One poster's advice to keep the antenna mount "upwind" was well said. Avoiding a chimney mount (on a working/operating flue) unless other options are not available is even better.

Best regards,

Jack Painter

Probably not. A single wire antenna connected directly to a portable radio is going to exhibit the highest form of noise and static known to radio listening ;-) Grounding a portable radio is going to do very little to affect this, but it could help and certainly won't hurt to try. But ground it to what? Certainly not your house AC grounding system. If you are going to the trouble of making a ground rod connection available to your radio then why not also use a coax feedline and a matching (Balun) transformer according to the estimated impedance of your wire antenna? That way you can truly "ground" the shield of the coax at the Balun, and grounding the radio itself will have some purpose then.

Good luck,

Jack Painter

Jack,
Like you say, fireplaces are bad. I think a gas furnace is a noop. The
previous owner of this house had a TV antenna on a chimney mount for
something like 8 - 10 years. When I took it down I saw no signs of any
corrosion, except possibly to the end of the wire.

Tam, good point. The flue gasses are corrosive even from natural gas, but
carbon would not be an issue there. Oil burning furnaces and fireplace usage

is where the carbon comes from, and the worst would be from wood burning in a fireplace.

Mickey did it, and now regrets it.

I never (except this time) open this kind of stuff. Well it contains
two harmony trojans. One puts ipconfigS.exe in your windows\system
(system32) directory and 2 registry entries. The other puts
zoneLockup.exe in the same directory and 1 registry entry. My anti-
virus program did not catch it, nor did PestPatrol or Adaware 6.0.
McAfee Freescan finds it but of course you have to buy the program to
get rid of it. I did a web search and found instructions about where it
was installed and removed the components. Note that the .exe programs
don't want to delete (access denied) so I used a program Move/delete on
boot GiPo@utilities, free for the old version.

http://gibinsoft.net/

You've been warned! I learned my lesson, I hope.

My God Jack. A ground wire will help with external antenna. Water pipe (metal ones) are nice, three feet of copper tubing pounded in the ground and connected to the ground lug, jack, clip, or whatever the connection is on the radio is all he needs. I doubt he will get a 40 db gain, but what the hell, he is only looking for as much signal improvement as he can possibly get without spending 5-6 grand for a tower and a log periodic that covers dc-daylight. Whats with this coax crap and balun wound to the frequency of the wire? You don't think he may want to change bands and freqs without running out to the "war and rewind the balun: an inexpensive mfj tuner between radio and antenna will do wonders. Why can't hams be elmers anymore instead of cryptic a-holes to the new guys?

ok Butch, point taken - didn't mean to be cryptic. I chatted with this friendly fella offline and will always offer to help anytime I can. This hobby has been very good to me. After almost 10 years of military-scanning (while in the Navy), I listened to my first HF via a Grundig YB PE400 - and was hooked ever since. I even connected it to rooftop discones (lol, but it did work) and I soon realized that little radio could copy Atlantic Ocean search and rescue comms the USCG was missing. Six years after that I now operate a coastal station from my home, handling cutters, aircraft & SAR up to 3,000 miles way. So I'm reminded of what can start from a little HF-portable with wire around the windows (and no ground)!

Wes, that guy Lombry is totally QAZ, which has long been the Q signal for 'lost
in a dense fog between two layers of thick clouds'.

That was a little over the top, wasn't it? One of the problems in here is that a newbie can get scared off *really quick* by some of the answers they get.

My advice to Wolfee would be three things. Put a wire out the window, and see what happens. There will probably be some improvement, and you can have a little fun by experimenting with the length. Use the ground. Ground it to a water pipe or if you can, to a rod stuck in the ground. You can even try a counterpoise long wire on the ground terminal instead of grounding it. Have a two wire setup.

Some of these things will work okay, some may not. But have fun experimenting!

666. power pole as a coil form for 160meters

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-23 17:14:40 UTC
From: Dennis Kaylor <k4oxg@tampabay.rr.com>
Message-ID: <4IbMc.56215$IX4.7440990@twister.tampabay.rr.com>
Source record: 92187

hello all
i have a power pole in my yard no linger used by power company and cut
down to 10 feet tall
what i am thinking of doing is to make this pole a monster sized
hamstick type of thing
use the pole as a coil form then put a radiator up top
so do you all think of this will it work will be it an efficent antenna
and how many turns of #12ga wire would it take?
thanks

667. Combining Cell phone Yagis in different directions

Newsgroup: rec.radio.amateur.antenna

Hello All,

I see a strange offhand way of responding to either Thierry's
criticism of Reg (which is pointed but accurate) or his own offering
of ground at his web pages, as containing no actual response to his
topics.

Reg offers us vanity software that is wholly useless by his own
admission:
"Remember the accuracy of performance predictions depends on how
accurate you know the soil resistivity and permittivity in the
vicinity of your antenna."

Even Thierry is savvy enough to have read Reg's scribblings that such
information is largely impossible to obtain except at the surface's
thin veneer - which is immediately confounded by RF penetration
(however meager) thus plunging knowledge into ignorance once again.
As such, this software by abstraction, and Reg in his usual temper,
mocks any attempt to be useful.

And this leads us to Thierry's own efforts at the pages offered. In a moderate scan of its content, I find it is composed from several references: ARRL, RSGB, FCC, and rraa. Oddly enough, fairly the same sources used here. I further note that Thierry has not invented any new physics to explain anything, there are few imaginings that would pass as dreams in the night. In fact, his coverage is commonplaces assembled into a coherent topic that does little to wander off into arcane math or the mysticism of calibrating mud.

Frankly, I find that Thierry has posed questions and taken advice in this forum and turned it into product at his web site in an effort that is truly in the spirit of Ham radio. I have further noted over a span of time, that Thierry's work has evolved and improved as he has studied the subject. If there is any criticism of his work, it would be best served to respond to specific issues and realize that in the long run error will find its way back to its source - HERE.

Hi Kent

Very workable. Odd multiples of 75 ohm coax to the antennas with a T connection at/near the phone.

There are also power splitters/combiners available for phasing antennas available. Will be more expensive though.

Personally since you are talking 180 degrees, I'd put together a bidirectional antenna though. The possibilities are endless here!

Cheers Bob VK2YQA

Hi Dennis, any thing will work, just not too well. The problem as I see it is with a 10' coil form about 1' diameter filled up with #12 wire is the self resonant frequency will be below 160 meters. This will make it not work as a loading coil. Of course if you made the coil self resonant on 160 meters it would not exhibit reactance, and you could load it, but it would be lossy with low efficiency.
To get any kind of efficiency on 160 the radiator has to be long, the loading coil large and hi-Q. Also need a good ground system. Maybe you could wind enough wire in the pole so that self resonance was double 1.8 mhz, add a stinger or top radiator and some top loading to bring the resonant freq. to 1.8mhz and see what that would do. Still not very efficient, even with a good ground.

672. Re: Performance of a system of Ground Radials

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-23 21:49:54 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <cds162$p7v$1@hercules.btinternet.com>
Source record: 92193

No-one will disagree that the efficiency of a vertical antenna is very simply Rin/(Rin+Rgrnd),

where Rin is the resistive component of antenna input impedance and Rgrnd is the resistive component of the ground electrode input impedance. The same current flows into each regardless of phase angles.

These measurements take into account the whole of the near field of the antenna and exclude the far or radiation field. Any small, if any, improvement due to extemely long radials MUST be considered to be within the far field with which we are not presently concerned. They play no part in antenna radiating efficiency which is a self-contained parameter.

The measurement of interest is the ground system input impedance such as at the focal point of a system of radial wires.

It should be perfectly obvious (except to some old wives) that radial wires are lossy transmission lines and as their length increases the input impedance tends to decrease. As with all lines the input impedance eventually converges on Zo.

With a lossy line, i.e., high attenuation, Zin converges on Zo fairly rapidly. Having converged on Zo any further increase in line length results in no further change in input impedance.

If there's no further change in input impedance (or the resistive component thereof) there can be no further improvement in antenna radiating efficiency. Thus we now have a practical limit to the useful length of a set of radial wires - or just one wire treated as a counterpoise. (A ground rod is just another short, thick wire.)

The situation is calculable. It is necessary first to find the attenuation and phase delay (or velocity factor) along the line at the lowest frequency of interest.

There is no point in having buried radials any longer than about 10 dB because the input impedance at that distance is within 10 percent of Zo or better. Or there could be some other calculable rule of thumb which would keep Lord Kelvin happy.

Having set a maximum on the length of radials the actual ground loss resistance depends on their number. And ultimately, of course, on soil resistivity and permittivity which involves some unavoidable guesswork. But that's quite normal when it comes to laying radials.

Or indeed to all other sorts of antenna predictions involving the ground and other obstructions, no matter to how many milli-bels the calculations may

have been computed to. Radio is by far the most inexact of ALL the engineering sciences.

But after all said and done - it does work! Even EH.

Reg, G4FGQ

Don't use a wideband combiner. Use a VHF/UHF diplexer. It's not because the diplexer has lower loss than the combiner. It's primarily to prevent the possibility of ghosting.

A VHF antenna can pick up the (unwanted) UHF signal from all sorts of directions (albeit somewhat inefficiently). The UHF antenna will receive the (wanted) UHF signal only from the direction in which it is pointing. The VHF antenna could pick up the same UHF signal bouncing off a hill, a building, or anything else. This unwanted reflected UHF signal will arrive later than the wanted signal received on the UHF antenna, resulting in a ghost to the right of the main picture.

Incidentally, the same argument is probably not quite so true 'the other way round', ie where a VHF signal picked up on a UHF antenna causes a ghost on a VHF signal. The UHF antenna WILL pick up a weak VHF signal, but only from the direction in which it is pointing or pointing away from, and not from other directions. Assuming that the two antennas are pointing in the same direction, the VHF signal received on both antennas will arrive at the same time, and you won't see any ghost (no matter how strong it is). However, this is all rather academic, because you have decided to use a diplexer!

Cheers,
Ian.

Note the "as usual", which I take to mean that the totality of Reg's
software is useless. This is bullshit.

This is from a guy who used to get his panties all bunched up (I don't
know how to translate the idiom to French) because the SWL QSLs he
received weren't all four-color with free money taped to the
"obverse."

You may disagree with Reg on a personal level, but many of his
programs are quite useful and entirely adequate for ham use and don't
suffer from the bloat that passes for software these days.

|

|assembled into a coherent topic that does little to wander off into
|arcane math or the mysticism of calibrating mud.

After my moderate scan here is one example of "coherence" chosen at
random by throwing a dart at my computer screen:

Quote:

"However, at radio frequencies the feeder having an appreciable length
compared with the working wavelength, it will also radiate power as
the antenna. Our objective is thus to minimize the unwanted radiation
from the feeder, in order to transfer as much power as possible to the
antenna with the less losses as possible.

However, without care the power lost by radiation in the transmission
line can be much higher than the resistance of conductors and
dielectrics. If we cannot always prevent power loss, we can easily
avoid loss by radiation."

End quote

|span of time, that Thierry's work has evolved and improved as he has
|studied the subject. If there is any criticism of his work, it would
|be best served to respond to specific issues and realize that in the
|long run error will find its way back to its source - HERE.

You got it.

Quote:

"A perfect theoretical line shows no resistance. However we know that
all electrical circuits apply the Ohm's Law... That means that at
radio frequencies all circuits display some resistance, that mainly
depends on the input voltage."

End quote.

op cit

So maybe if Thierry apologizes to Reg, Reg will write him a program to do Ohm's law stuff.

Warmest regards,

Wes

Yup ... of what I understand, you'll get better results top loading it and putting in a good ground. How about using the pole as a sturdy base for a tilt over mast rather than a coil?

He probably will. This stuff has gotten kind of old and I'm more into
woodworking now. I just pop in once in a while when I'm waiting for
the glue to dry.

I must say that Thierry does a beautiful job putting together his web
site. My gripe is with the flawed technical stuff. The fact that the
site is so nicely done might make the unwary believe that the
technical stuff is as good as the web site. Clearly, it is not.
Pity.

Furthermore, much of the material is by someone else and often used
without attribution. This latter point is a pet peeve of mine since
I've had it done to me.

And another consideration about your "Pole Stub" : if pressure treated creasote, or just creasote coated, then MIGHT get it to work, but, IF IT'S TINT is slightly GREEN, then this pole was perserved (cant remember the concoction , PENTA?), with a metallic-oxide preservitave. This will have ramafications on the inductive value of any coil you wind (kinda like a ferrite slug in a coil form)! Jim NN7K

Hi,

Question to users of Hi-Q antenna (Stealth II 2.5-80 MT, etc)

To complete an article devoted to mobile antennas, I would like to know what
is the maximum distance you have worked using such Hi Q antennas ?
I know for example that some amateurs from Illinois reached Hawaii and
Brazil and receive a S59+20 dB report at a distance of 150 miles (200 km).

Do you have an experience in Europe at 100 W PEP in SSB ?
Did you reach Middle East or North Africa or work some true DX station
located over 5000 km (8000 miles) away ?
Id you did, under was conditions (propa, height, etc)

Thanks in advance

Thierry, ON4SKY
http://www.astrosurf.com/lombry

I had some answers by direct posting
Some K and VE users reached bare foot (100 W PEP) over 30 DX entities
worlwide from GB, ON, UR, TI, ZS, VK, ZL... Incredible antenna.
But I 'd appreciate the opinion of european users, if they are, as I live in
ON and LX (where this call can help, Hi).

I have a HiQ/Stealth 4-160. In my 100W mobile, from California, I easily
can chat with
ZL and VK on 20 meter SSB and get 59 reports. That is
a distance of around 10000 miles. JA (6000 miles) is duck soup from here.
Europe
is little harder, but I have worked lots of Europeans as well. Same for
South America. Never worked the Middle East mobile, it's tough enough
from home. Occasionally, I work a ZS under good condx. That's 11000 miles.

It's not distance that matters so much, it's whether you have to go over
the pole or equator. The latter is more difficult.

Note that on 20 meters, only a few turns of the Stealth coil are in use, and
probably any 13 foot antenna would be equivalent. (I have an 8.5 foot CB
whip on top of the Hi-Q which is 4 feet). Where the Hi-Q antenna becomes
important is on 75 meters. I have heard people working JA from the
west coast USA with Hi-Q antennas, although I haven't done this myself.

Hi,

ZL at 100W ? Oh Oh!...
Do you experiment more QRM/QRN that using a horizontally polarized antenna ?

> Europe
> is little harder, but I have worked lots of Europeans as well.

It is a good news however. Its seems to work better than a 6m high vertical
e.g.

How do you drive your path with an omnidirectionnal antenna, excepting when
you use the grayline ?
You cannot say you go by the pole or via the equator, excepting when a JA or
a PY answer you maybe... ;-)

Indeed. I compare also its performance to an ordinary dipole or longwire
20/30m long tight quite low (4-5m high) or to a small vertical 6m high with
flexible radials.
But the Hi-Q is really compact and can be erected much easier in the field
too for /P operations too.

The sole problem is its price but a good vertical (but cumbersome) is often
more expensive. So it seems to be a very interesting product compared to
many low-end hamsticks or even to many vertical so-call performing (in

period of high solar cycle, Hi !)

I hooked up with VK0TB (Antarctica) while mobile in London many years
back on SSB but I'm afraid I was not using one of Charlie's fine
antennas, nor was I running 100w.

Don't know the mileage.

Does that count?

I thought not:-)

I did it too using a dipole, but in this case I speak of Hi-Q antennas, not another brand.
Thanks for reading the question....

I would like to hear from anyone who operates with a windom antenna. Are there any advantages of putting a 4:1 balun at the feedpoint vs feeding with ladder line? I have about a 200' run from the shack to the trees it will be put up in. It will be up about 40'.

My plan is to concentrate on 10, 20, and 40 meters.

Any thoughts?

Thanks,
Doug/KC8YEC

Hi,

My 2 cents contribution;-)

A windom is an old design replaced (or completed) today with the carolina
windom that uses a matching section and coax.
The original design is simply fed with a single wire transmission line but
it is the source of RF radiation, up to into the shack. This is not the best
solution.

Your alternative is much better, and the ladder line is know to offer the
least loss also.

Hello,

What does "Q" stand for as I can't find it in any book as a unit of
measurement. It is often used as in "high Q RX". But what it is a measure
of?

Hi,

Note that it is always easy to criticize in armchair that to write something about a subject, even compiled or based on his own experience.
I would like to see more text and article from all contributors of this forum who created a website.

When they are not deeply flood in shematics and electronics buildings, I am often surprised by the poor quality of the comments and opinion of these amateur webmasters. Hopefully many others tend to provide a quality information, and I try so, sometime, as someone told, after asking some more explanations on forums or in clubs if the subject looks really confuse and if I have no book to refer to.

Now, I never said that the "radial page" was perfect. More I read or hear comment about radials and counterpoises, more I note that they are confusions and that the subject is really difficult to manage to get a clear view of all possibilities involved by the influence of ground and other thinks like lenghts, etc.

I used several models of vertical from 6 to 9m long, with radials or counterpoides and I know their effect, so this page was not create from scrach with useless information.
This is the first time that someone consider one of my article as negative or almost, and I am not sure that it is.
But as someone told it, I will check it. I will maybe clarify some "foggy" sentences and review other comments. I never consider an information as permanent or complete, all the less speaking of antenna where results are largely depending of the experimentation.

By the way, as you speak of QSL, speak about them.

I am still free to collect 4-color QSL I beleive... like some other collect
stamps or coins, and if I haven't tell you before, I do not sort vertically
the QSL that are not colors... Yours are maybe in your cellar or in your
attic now, mine are at a few meters.
I maybe respect more the ham spirit than you beleive.

But worst, up to now and since I work on the air - a lot of years - I answer
to ALL QSLs, even to SWLs, what is far to be the case to many hams of your
country. Some I contacted by email answered me that they never answer if the
SWL does not include at least 3 stations heard !
But this is not to get an award OM, but simply a QSL, so next time ask them
to answer to each SWL's QSL. This will respect the ham spirit that you sign
in succeeding your ham exam.

Thierry, as even the most critical observers have noted, your website work (and it IS your work, regardless of the often referenced and concept of similar writings) is appreciated on a scale so wide that few would argue against its immense usefullness to the hobby.

The material presented and fashion that you offer it is four-star, in my opinion. And I do prepare websites for consumption by the hobby generalists and specialists in some areas. That a website can provoke discussion, debate and improve overall understanding of principles and theories is perhaps the highest accolade it's owner could receive. You achieve that in my opinion.

I have little doubt that you do maintain information on the website that requires updating as current practice and development in the field do change. And this is the perfect forum for that kind of discussion to be held. Sometimes we have fun in the diversions, that is as long as we acknowledge the work by all who post here. You are all, in my opinion, very valuable to the hobby and the improved performance we all seek.

Best regards,

Jack Painter

Mmm...
If you have only find THESE "errors" I am satisfy, so-called 2 or 3x 5 lines in 1.2 GB of data, it's OK, "nominal", even if all (true) errrors must be corrected.

NB. If you are able to correct the text, as you seems to tell it, please do it, and send me an email. You will help the ham community in the same occasion.

Correction, I never read (and I wrong because those books are probably very
well done) any book from RSGB, FCC or rraa as you state peremptorily,
excepting, and partly, the ARRL antenna book, and I quote it in the related
text dealing with radials.

Why, could you invent or do you know someone able to invent a new physics to
explain how work an antenna ?
IMHO this is not necessary as long as we use it as today.

Hi Jack,

Glad to know your opinion.
I am not really offensed by someone who is criticising (negatively) my work.
All depend on his tone and the way he describes the "problem".

ARRL, UBA, a VK, a JA club, some manufacturers and some professors here in Europe to name a few people have referenced my website and others use its contain for public activities, so I think that I do no more really need other supporters (I do not speak of you) to know that most of my articles are interesting and correct and contain a more or less useful information (all depend on your level of knowledge in this field).

If some readers are sceptical, they can check my guest book that confirms the level of the site aswell as the tens of emails I receive each week in my different mailboxes. No one is negative and all readers congratule me or ask for more information, that I provide them.
Occasionally (once every... 3-6 months maybe, some readers, contrarily to Wes, highlight an error, that I correct immediately.

I regret however that there are always people ready to fight instead of sharing their knowledge with others.
Hopefully we are not oblige to live with them, excepting sometime to read their post, et encore.

I regret only to not be so fluent in English than I am in French to write these ham articles in a language and grammar as good as the one I used to write the French ones about astronomy and other sciences. But I improve, hopefully ;-)

NB. In some weeks I will be again on the air around 14.180-14.240 MHz with the call LX3SKY beaming US for the county award...
Hope to work you and many of your friends (between 13-19 TU on weeks days).
Keep an ear tuned to "Lima-X-ray three sky"... ;-)

Yes, and here is how you spoke of them in rec.radio.amateur.dx

Quote:

"That can be a problem as QSLing direct I pay 1 GS, maybe more, for a
QSL, most being sent to DX or to their QSL mgr, waiting impatiently
the return.

Most hams (to say, about 60% of my QSL), send an ordinary QSL on
vellum bristol with text box filled out on front. On these QSL verso
is often blanck.
For the same price I prefer to receive a colorful QSL without ink
marks or crossed out (erasure) , showing a polychrome picture on recto
and the QSO information on the verso, and still more when this is a
far country, a DXpedition or one of the 100 most wanted. But this is
not always the case, even QSLing direct."

End quote.

Furthermore, when a German ham chided you about your attitude, you
called him a racist. That's a ploy widely practiced among some people
in this country to deflect justified criticism. Doesn't work here
either.

|
|I am still free to collect 4-color QSL I beleive... like some other collect
|stamps or coins, and if I haven't tell you before, I do not sort vertically
|the QSL that are not colors... Yours are maybe in your cellar or in your
|attic now, mine are at a few meters.
|I maybe respect more the ham spirit than you beleive.

Considering the quote above, I find your newly developed attitude hard
to believe.

|
|But worst, up to now and since I work on the air - a lot of years - I answer
|to ALL QSLs, even to SWLs, what is far to be the case to many hams of your
|country. Some I contacted by email answered me that they never answer if the
|SWL does not include at least 3 stations heard !

Not my policy, but not unreasonable, considering you could watch an
Internet Cluster and get a station call and who he worked, at what

time and freq.

|But this is not to get an award OM, but simply a QSL, so next time ask them
|to answer to each SWL's QSL. This will respect the ham spirit that you sign
|in succeeding your ham exam.

I started collecting SWL cards 50 years ago before I was licensed (46 years ago). Therefore, I answer *all* cards received in the same manner as received. Although I'm dismayed at the number of US hams that have been sending me cards from Field Day without SASE. Any more will possibly go in the trash.

BTW, a quick check of my log shows that I QSL ONL 8956 and ONL 9514. Maybe friends of yours?

Unfortunately, my QSL is only one color, so if they are friends of yours they might be unhappy.

Yes. It is proper form to say, "Published with permission of ARRL" or
some such.

Or, The ARRL Antenna Book has this to say, "....."

That's only a half measure what with a few miles of water between you
and ZL/VK, and anyway 20m is cheating.

We have to talk right around the globe.

Have talked on many occasions with VK on 160m mobile SSB.

Some say "if you can't hear them you can't work them.

I disagree. If a 'G' sideband 160m mobile station is heard down under
and they cannot get an answer on the first call, they simply flick the
switch and run the same power as the mobile to make sure they get
through on the second call.

Weirdest contact was mobile to mobile with Nome Alaska, it wasn't just a
different time zone, it was a different day!

Scroll down to see a photo of the 'old' top band crowd. I'm in the pic
with a 160m Texas Bugcatcher antenna and capacity hat antenna on the
left:

I don't find any problem with Reg's discussion of ground characteristics. It is true that the depth (no pun intended) to which he approaches the problem is beyond the ken of most amateurs considering their own ground situations, but I find it hard to understand why Richard considers it 'mocks an attempt to be useful'. I learned something from his discussion.

I would add to Reg's discussion that when there are enough radials, their length should extend only to the point where the returning displacement currents from the vertical radiator are so small as to be in the range of diminishing returns.

The word was erroneous and corrected in another post. "useful" is the
correct word... and I sent a personal email to Reg to confirm this as he
already shared with me his dipole software and some others that helped me to
caculate some formula in the fields when I tight some wire antenna, etc..
sorry ;-)

I used a homebrew Windom during Field day. This version had the 4:1
Balun, and worked very well. Of course that is a subjective opinion, but
I can say that we could hold a frequency and run with it on 80 and 40
meters, and were even generating pileups. (at 100 watts) I would not
hesitate to recommend one. Multiband and no tuner. It won't make coffee
for you tho'.

Why would you recommend a 50 ohm, $50 or more Comet duplexer (diplexer)
for TV antenna use? The correct 75 or 300 ohm diplexer is only about $5.

about 41.4 meters total with the small side about 9.66 meters. Height
was around 12 meters above ground. Best SWR was a little low in the band
for us, but the internal tuner tweaked that easily.

Short answer 1) this is AMATEUR related page- as such , one assumes that
he needs the comet (or other brand DUPLEXER) so as to feed 2 (or more!)
bands with energy/and recieve on them at the SAME TIME (or listen to
one, while transmitting on the other at the SAME TIME!

Short answer 2), for TV, you WOULD ONLY USE A SPLITER (just dont try
TRANSMITTING into it-- as you would toast the SECOND RECIEVER tied to it!

Hi Walt,

It is my assessment alone as Thierry has begged problems of language.
My having recently attempted to use Babel fish to correspond in Dutch
reveals it takes more than a table lookup program to be intelligent.

Mark it as personal differences. Wes has revealed his with Thierry,
but he has also revealed two Howlers of error that stand correction.
I can trust Thierry to correct them, but Reggie is another matter. If
this piece of software were announced to this group sans Reggie's
imprimatur, he would be the first to denounce it as useless beyond the
simple advice to stick down a handful of radials and let it go. The
archive groans with the weight of such responses from him.

At the base, this attends a deeper issue (puns intended) that Reggie
religiously (a trollish religion) refuses to enlarge upon. It is what
I call the "calibration of mud." Reggie will not respond to this
directly, but I am sure he will offer that this point is rendered by
me in an English that has been corrupted by the CIA. Hence his
trollish delight at deflecting his own topic.

Reggie has offered to this group that it is a very simple matter to go
out into your garden, scoop up a cubic (choose your own unit of
volume) of dirt and discern the basic soil characteristics that would
then be entered into this fascinating work of art just released. Does
he "teach the art" of this necessary skill?

By his own standards in the excellence of scientific enquiry the
"teaching of the art" is part and parcel to the precepts of Heaviside
and Kelvin, and yet Reggie demeans them both to the level of my
mocking eponyms of Plushbottom and Kelvinator by choosing to offer
solutions rather than knowledge.

Is this latest piece of software anything more than a virtual look-up
table? Does it educate in the principles of how to determine local
soil characteristics?

I would be glad to be wrong because Reggie puts in 10,000% more effort
than so many scribblers here who resort to cut-and-paste philosophies

of others. I do not fault Reggie for errors, others have found them and reported them here. Their proportion have been slight to the number of bulls-eyes. I am holding Reggie's feet to the fire of his own "standards."

He came into this forum defaming software as a cheap crutch, error ridden and a contemptible substitute for scientific thought. As having practiced as a software artist for several decades, I agree wholeheartedly and ask him: "show us your work." :-)

> thanks

If you decided to do this, it would be best to wind the coil at the
top of the pole as a lumped coil. Than add the stinger mast on top of
that. If you used 10 more feet on top, it would be center loaded. This
should improve efficiency over winding the coil on the whole length of
the pole. The current distribution would be improved.
The radiator below the coil, could just be a wire running down the
pole to the base. I would add a cover to the coil to keep it and that
portion of the pole dry. If the pole is 1 ft dia, you would need about
35 turns +-, if you used the upper 1 ft section of the pole as the
"coil" area, and the stinger was also 10 ft. "20 ft total". A taller
stinger would be even better naturally. Top loading wires attached to
the top of that, even better. Efficiency will depend largely on the
ground radial system you have. If you had a 2 ohm ground loss, the
efficiency would be about 26% with the 20 ft version. Just doubling
the stinger to 20 ft would reduce the coil turns to about 28, and
raise efficiency to about 40-41% for the same 2 ohm ground loss. Get
as much top capacitive loading as you can for best results. MK

Hi,

When I speak about Hi-Q, I speak about the brand (www.hqantennas.com), not the other antennas offering a high Q... But this is not a problem as loops interest me too and enter in the subject due to their overall high Q.

You could win the 1000 miles per watt award with such a QSO... ;-)

Indeed, this is far to be impossible with a loop. Here is a personal experience among others that could interest some readers in search of a stealth antenna suited for both ragchewing and DXing.

When I was using both a receiving and a transmitting magnetic loops (now I use a dipole and a beam), for demonstration purposes a DL friend of mine worked with a german WIMO baby loop (Q=1100) of 1m in diameter made of alu 50, an impressive antenna that weighted 12 or 15 kg !

Placed in my garden, on top of a mast about 6m high, from LX we worked ZK1USA at 100W in SSB on 20m and at other occasions we worked a T2 and several H4 stations too.
When we published the ZK info on the cluster some DL readers didn't beleive it was possible as they didn't even hear that remote station ! Of course many others did. But I don't know if they used a beam of another antenna less directional. In all cases in our QTH, all these stations arrived well even using "poor" receiving systems like a simple receiving loop or a longwire looking like a beverage...

We worked ZK by 08 TU at summer, thus hours after the grayline in Europe when it was night in ZK. The signal we get was weak, about 54, sometimes weaker, with QSB but the QSO was worked as the QSA has a strong audio, quite amazing for a so long distance.

In fact I compared this result with my first QSOs worked from LX to JA using a 3-ele beam at 12m high with a lot of QRN on the frequency due to the solar activity. There was some QRM too very close, but I could work the JA without problems thanks to my RTX DSP (mp 1000 m5).
So in some respect we can compare the result of a performing loop displaying a high Q to a 3-ele beam equiped with traps (old Fritzel model) placed in front of open fields at 200m ASL.

For short, generally speaking I am very satisfied of magnetic loops too and I recommand it to all readers who cannot tight a long dipole, a true 1/4L vertical or install a beam due to restricted place or discretional reasons. Only (small) constraint such an antenna needs to be powered and radiates a lot of magnetic field, so placing it 10m away of human beings is a good safety distance and preferably outdoors.
1m in diameter is really stealth, and easy to stole too ;o(if you don't take care. With this wimo loop we worked many DX stations on all 6 continents. It is not as performing as my 3-ele beam, the signal received is often weaker than on the beam and the gain is quite low, but due to the F/S rejection and directivity, IMHO it is far better than an ordinary dipole, even rotary (but all depends of its height and length too of course). To be complete say that of course we can get similar results or even better using wire antennas like a rhombic 2-lambda long, etc, but only people who never used a loop can say it is a little performer; this is all the contrary, it is maybe not a big gun but a good one anyway able to fight against small beams.

But I stop here this too long review... ;-)

Hi,

Thanks for your answers.
Have you already compared the results (signal report and radiation patterns)
of your Windom with a multi-band dipole as long or with a Carolina windom ?
I 'd like to know if the design of these both wire antennas, although
different, give similar results in both signal strenght an directivity
(takeoff angle), or if someone else have such experience and could answer me
?

Thanks in advance

Hi Doug,

I've been using an OFCD 130' fed about 44' from one end 4:1 balun at
fed point and it's up as a sloper about 45' at feed point. All I can say
is it works ok for me. Most of my activity is 80-30M but occassionally
I operate 20 --10m. I find that the thing has an acceptable SWR on most
of the bands and the auto tuner takes care of the tuning quite easily.
Is it as good as a dipole I think so and it produces contacts.. There is
no magic here though.. it is not better than a dipole most of the time
either. but It allows me to have one antenna for all bands that tunes
well with the auto tuner. If I had a balance tuner I'd go all the way
with the Ladder Line.
On my set up I use a choke balun on the coax before it enters the shack.

73, Dave

Hi,

20m is what ? I do not appreciate such a word in the mouth of amateur radio
to whom the ITU gracefully gave access to this band and many others. Other
people fought and are always fighting to preserve our rights on those bands
!

Do you prefer that someone deny to the ham the access on the 20m band and
give it to the army of a public service ?
To prevent this to happen don't blame those who are using this band !

And I think that yourself you use it, and many readers work on the 20m ch...
band as you said to get their top 10 DXCC or any award.
This is the most used band and most easy to work DX too.

So don't spit please in the soup and on the most used band because it is as
crowed sometimes as the 40m one when you want to work with it.
NB. If this is the case, a beam antenna and a performing DSP receiver system
can solve this problem.
This ch... band as you qualify it is on the contrary a proof of the good
health of our hobby.

729. Don't be afraid

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-25 14:02:15 UTC
From: Brian <brian@iquest.net>
Message-ID: <H3PMc.15471$Qu5.13328@newsread2.news.pas.earthlink.net>
Source record: 92050

As a long time cave dwelling SWLer, I had to work with less than perfect antennas just to receive any decent signals. I've been out of the cave for a long time now but in my housing addition I still face antenna restrictions. I operate QRP (5w or less) on 15m, 20m, 30m, and 40m using CW, and ocassionaly PSK31. I am using a half wave dipole in my attic, cut for the middle of 40m. With my Ten Tec 291 antenna tuner, my K1 is happy on those four bands.

My attic dipole has the last 8 foot on each end, bent at a 90 degree angle, since my attic wasn't long enough to accomodate the full length in a straight line format. At the feed point I have a loop of about 8 turns of RG8X coax acting as a choke and then the coax feedline goes to my operating position and terminates into the Ten Tec antenna tuner.

Run the math and this is a poor radiator compared to a set of stacked beams at 75 feet. <grin>

I have managed a WAS in 1999, 2001, 2003, and I have about 9 left for this year. Mixed bands although 1999 was on 40m.

When camping with my scout troop, I have used wire in the trees with a wire on the ground and have been able to make QSO's. How about my DXCC efforts?? Sadly, I have only managed to log 52 DXCC entities so far. I put this system on the air in the fall of 1998 when I got back into HF operations.

Best DX on the attic dipole was Reunion Island on 4w from central Indiana, in 2000, on 30m.

So, if you have a bad place for an antenna, try it anyway. It might work enough to at least get you on the air with a QSO or two. The nice thing about outdoor portable wires is if it doesn't work here, move it over there.

Hi,

FYI here are two propagation software that look rather complete and using a pretty and user-friendly GUI. Let's try them.

First the simpler, DX Toolbox :
http://www.blackcatsystems.com/software/dxtoolbox.html (zip to explode and run)
then the more complex one, Win CAP Wizard :
http://www.taborsoft.com/wwizard3/ (come with a setup).

For WINCAP read well the installation notice BEFORE to install.
Both work completely in a different way but each deserve a try.
Of course they request some basics in propagation...

Brian,

Nice post!!
Too many times we see folks posting here with their anguished concerns
about putting up some XYZ antenna in a less-than-perfect environment.

"Woe is me! How can it possibly radiate?"

Well, my (un-posted) retort has always been: "Just how well does it
radiate while laying in pieces, in a box, on the floor of your garage?"

Again, nice post!

I've been using a 66 foot dipole fed with 600 ohm ladder line up at 35 feet since about February. The antenna is strung between a Pine tree in the front yard and a Sycamore in the back yard. I love this antenna. I've been running QRP at 3 watts and working a lot of DX even with crappy band conditions. I only have access to 20 and 40 meters. The antenna is "flat" on 40 but about 2.5/1 to about 3/1 on 20 meters. The feedline is 50 feet long although I don't need that much feedline. Does anyone have a formula for calculating the length of feedline for 20 meters without screwing up 40 meters? I'm hoping I can cut out a few (10) feet and get this thing a little flatter on 20. At present the ladder line comes down at right angles to the dipole and is actually laying on the roof of the house.

When I used to use coax fed dipoles I would add pigtails to the ends of the dipole to change the SWR but on this antenna I can't easily get to the ends to make this sort of adjustment. So I'm having to work with the feedline and the tuner. Oh, yea, the tuner is a Dentron Super Tuner.

Thanks for the help.

Hi Pat, if you are using a tuner with your 66' dipole and 600 ohm feeder, then you should not have a problem getting a near perfect match on both 20m and 40m. You may need to try other tuner settings on 20m to get a better 50 ohm match. If you feed a 66' dipole with 52' of 600 ohm line (3/4 Lambda) on 14.2 MHZ you should have about a 1.2:1 50 ohm match. If you increase the feed length to 68.4' (1/2 Lambda) on 7.2 MHZ you should have around 1.5:1. If you could vary your feedline length, then you would not need a tuner. This is a common way to avoid using an antenna tuner.

OK, I probably won't be the first one to tell you, "Don't do that!"
But, IMO, the Bad Effects of that would be seen on 20M to a greater
extent than on 40M.

Message-ID: <10g8j3i7qk8pi51@corp.supernews.com>
Source record: 92061

I came across this in searching for a multiband, HF antenna. The designer says that it is, "An effective 10-20m DX antenna for deed restricted lots..." and may be found at:

http://pages.zdnet.com/radio_k7zb/id8.html

anyone, other than the designer, have any experience, or thoughts on this design?

I am renewing my interest in amateur radio after being away for a number of years.

Thanks.

Thomas

741. Improving performance of 102" whip + AH-4 setup

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-26 00:13:09 UTC
From: micropower_fm@hotmail.com
Message-ID: <45cc755c.0407251613.53798cf7@posting.google.com>
Source record: 92062

Hi -

I've had a 102" whip coupled to an Icom AH-4 tuner for a while now on my van, it gets out well enough but as always, I can't seem to leave things alone :) I've got the whip coming out of a bolted-on ball mount off the quarterpanel, about 40" off the ground. Here's what I was thinking...since I can't go much bigger on the whip (at least while moving), what about adding a center loaded coil to the antenna, and tuning it via the AH-4? I've got about 120" to play with to make a max height of 13'6".

What about a Texas Bugcatcher (or similar) open air coil, mounted on a three and a half foot mast to get it over the roof line, and then go the rest of the way with a whip. How much inductance do I need to be able to let the tuner go from 160m-6m?

Any other suggestions? Crazy ideas I could try? Thanks in advance.

FYI the two antennas are going to be fed into a cell phone repeater that
will have its own antenna. We need to cover directions 180 from each other.

An externally tuned vertical should work FB. Not up to a beam, but
better than most mobile antennas.

Agree- no K.W. with 3, or more Els, but a verticle can adjust hights, and 2 RADIALS for a COUNTERPOISE! (corse, could do Thierry's trip, just DOUBLE the lengthof the driven el,and feed from a tapped, PARALLEL RESONANT tuned circuit (antenna at the coil/cap end, VERY HIGH VOLTAGES!), to make it a 1/2 wave antenna (end fed), no radials required (but remember, TWICE as high) ! For openers, NO it wont work-- to get 2 antennas AT THE same FREQ range
to work, requires at minimum, a power devider, or at least 2- 75 ohm 1/4
wavelength(or odd multiples thereof) lenghts of coax to that 50 ohm
feedpoint ("TEE Fitting") and, dont forget to figure in the VELOCITY
FACTOR ! See any reference about "Stacking antennas", or "Impedence
transformers". This MIGHT work, IF the repeater has isolation-- not
just two cell phones tied back to back, then fed into the same coax !
Mean full repeater- complete with cavities, filters, ect! Jim NN7K

Kent

Do you mean that the two Yagis will be fed together to produce a radiation
pattern with two beams pointing away from each other??
I would submit that a bidirectional antenna could be built that way.

751. Asking for help with designing a VHF balun

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-26 02:03:00 UTC
From: Jerry Martes <j.jmartes@verizon.net>
Message-ID: <oDZMc.11512$qT3.3772@nwrddc03.gnilink.net>
Source record: 91972

I'm trying to build a 1:1 balun with minimun insertion loss for 137 MHz.
I have never done this before and would like to hear from someone who has
some experience with building and using a 1:1 balun at VHF.

I've been trying to wind small coax inside ferrite toroids. The only
thing I can measuer on this balun is its impedance, but actually would like
to know its effect on the radiation pattern.

At this point in my tests, I can provide 300 ohms of highly reactive
impedance on the outer conductor of the "RG58" type coax. At the beginning
of this project I assumed that I could easily get much higher impedances.

Any information and advice will be appreciated.

Jerry

> different, give similar results in both signal strenght an directivity
> (takeoff angle), or if someone else have such experience and could answer me

No. Unfortunately, we only used the OCF dipoles in this case, and had
nothing to compare them with. That is why I had to remark that my
assessment was quite subjective.

Such is the problem with so many antennas. The user puts the antenna
up, makes some contact's with them, and "the antenna works well" is the
answer.

My only comparison with another antenna would be with an 80 meter
dipole used in a previous year with the same equipment. In that case
however, the transmitter power on the plain dipole was 1000 watts versus
100 for the OCF, hardly a fair comparison.

But I would have to say that we had no trouble making ourselves heard. The antenna shows now appreciable deficiencies compared to a simple dipole, and since it had the desired property of not needing a tuner on the other bands we were operating on, the antenna was a big success for the application.

DXLab, a free suite of 8 applications that automaticly interoperate,
includes the following capabilities for monitoring and predicting
propagation:

1. collects SFI, A, and K indices from up to 6 web-accessible DX clusters,
and displays high/low/last values for each over the last 30 days

2. uses the IONCAP engine and the current SFI to predict propagation between
your QTH and another location specified by lat/lon, gridsquare, IOTA tag, or
by clicking on a location on a world map; the prediction is shown as a
QST-style "bands open over a 24-hour period" chart, with the option to
display critical frequencies

3. displays the auroral region boundaries on its world map as a function of
the K index, along with your signal's great circle path; in combination, you
can assess the likely degree of auroral interaction

4. displays the solar terminator and computes sunrise/sunset times for your
QTH and any other specified location over any 30-day interval

5. allows you to assemble a schedule of IARU/NCDXF HF propagation beacons;
optionally QSY's your transceiver and optionally rotates your antenna to
monitor each beacon in your schedule while highlighting the beacon's
position on a word map

All DXLab applications are available via www.qsl.net/dxlab and several other
mirror sites.

756. UHF 5/8-wave vertical question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-26 06:14:03 UTC
From: Scott M <spamkiller@elp.rr.com>
Message-ID: <Li1Nc.22814$WP1.13838@fe1.texas.rr.com>
Source record: 91977
Cross-posted to: alt.ham-radio.vhf-uhf,rec.radio.amateur.antenna

I've built a 5/8-wave vertical for indoor use on 440 MHz. The radiator is 3/4" dia. copper tubing left over from a 2-meter j-pole project. The radiator attaches to the center pin of a SO-239 by way of copper braid wrapped around the end of the radiator and held in place by a hose clamp. The braid is attached to the SO-239 center conductor. 1/4-wave radials (drooping at 45 deg.) are attached to all 4 mounting holes on the SO-239 connector. The antenna is hung from the ceiling vertically and fed with about 12" of RG-8/U.
It works fairly well on RX and I can hit a repeater from indoors with 1/2 watt when I couldn't do that with a rubber duck. I get a low 1.5/1 SWR from 440-450MHz. Even still, I have read that there is capacitive reactance at the feed-point of the 5/8-wave vertical (fed from end) that needs to be countered with a small coil. Now if the impedence is really much higher than 50 ohms, my coax must be transforming the mismatch. How else would I get such a low SWR? As for the coil, how in the world do I determine the coil's required inductance and therefore it's dimensions? I have some formulas to figure the dimensions, but how do I determine the amount of inductance?

Gnome,
Ought'a work just fine. It's not so 'weird' of an
idea, lots of people do it. Maybe not with an 'AH-4',
but with other autotuners.
How much 'coil' or inductance for 160 meters? It
will depend on the length of the whip, but something
in the neighborhood of 200mH, give or take 50%. A
'top hat'/capacity hat would also help.
'Doc

759. Screwdriver antennas--Opinions?

I am very close to testing for my general ticket thanks to Gordon West's morse cassettes. I want to get an HF screwdriver antenna for my mobile in anticipation of adding /AG to my call and am looking for opinions/suggestions on manufacturers. What are the pros and cons? Do you have a favorite? Best place to buy?

Thanks for the input.

I had the two element version for a couple of years. It performed well but that was when the sunspots were a lot better. Specs are narrow on 20 but it handled a full KW across the band. I can't comment on gain but it definitely was directional. Mounted on a TV rotor it is easy to mount and turn. It is small enough, I can't imagine ice loading would be an issue although the SWR does change when it is wet. The coils are covered with a silicone compound but they are exposed and thus change slightly in the rain.

It is a compromise, I later switched to a full size tribander. If I were limited to something really small, I would get another one but if you have any way at all of using a full size antenna, it would be better.

That is exactly how I mounted mine using TV installation hardware and straps around the chimney. Higher is better but about 3m is all the mast you will be able to support.

Mounting 5m over the ground would not be a good idea. Too low.

>
> 73, Dave

The problem with OFCD dipoles feed with open wire line is that it's
un-balanced and the line radiates. That is the main difference between a
Carolina Windom and an OFCD. With a good current 4:1 balun the feed line
will not radiate. I designed the OFCD dipoles we used at field day and went
for the coax feed just to eliminate the feedline radiation. Simulation of
the antenna shows that it performs as well as a dipole on 80m, on 40m it has
the same performance as a 80m dipole feed with open wire line and a tuner
with less losses as the match to the coax is quite good. Remember tuners
lose about 10 to 15% of the power passing through them. On 30 meter it was

not very useable. 20m was good with gain over a dipole but the max gain was in 4 lobes at about 45 deg. to the line of the wire. 17m has a good match with the pattern having many more lobes as expected. It had not a good match at all on 15m and 10m was useable. Any multi-band antenna is a compromise and for our use at field day it fit the bill quite well. The antenna was 135' long with the feed point at 86' from one end through a 4:1 current balun. I would recommend using RG-123 or better coax to minimize the increase losses from the higher SWR on some bands. By the way I think that one of the reasons they worked well is that we had them up as flat tops not as inverted "V". That made the effective height 40' instead of something lower if they have be up as inverted "V", it does make a difference.

Do you want balanced input/unbalanced output, or unbalanced input/balanced
output? What frequency? What impedance?

Hi Russ
There are a number of folks who make good antennas.
High Sierra, Tarheel. Nott and Hi-Q are all good. There are others I've no experience with.
I use a 4' Tarheel with a 4 foot whip for 80-20; The 103" whip kept hitting overpasses on the interstate.
Also I run a big (5" coil) Hi-Q for 160 & 80 with a top hat and 103" whip; both antennas matched with an autoformer.
As a second antenna I run the small Hi-Q with a short whip to resonate at 6 meters at the limit.
The radio's a TS 480 HX. The truck's a Dodge Durango.
By all means use an analyzer, resonate the antenna and match the impedance.
I can almost nail the tuning by listening to receive noise.

I live in an appartment and the only kind of antenna I can have is one that is indoors. I have space for a wire antenna on a wall upstairs. I can't get in the attic. If I make a wire inverted V, the ends are behind furniture. Would it be OK to just make a V antenna, which gets the ends up the highest? Also, I know I'll get some flack for this but it's for 11 meters. I know there is too much garbage on there but I have SSB radios and would like to be able to talk to family members who are mobile.

Keep in mind that there is a 20 db loss if the mobile antennas are vertical and your's is horizontal. Try to keep the hot side of the dipole vertical and the ground side can be horizontal. For skip signals, it won't matter, but for local it makes a big difference.

Hi Chris,

Mount a mobile CB antenna to your balcony(?) and put a festive wind
sock on the end of it. It doesn't have to be strictly vertical; so
set off at a 30 degree angle would be consistent with the festive
camouflage. As for "non-inverted" V antennas, I would suppose the
majority of the CB crowd is vertically polarized and being cross
polarized with a strict horizontal would conflict with your desires to
contact friends and family.

You might try with a full wave horizontal or vertical loop. This
would run roughly along the perimeter of a room at the ceiling or a
wall. You may just wish to do all walls and the ceiling with an
antenna switch as this would have distinct nulls. As it is distinctly
unlikely that you would have 12 foot ceilings, such loops are not
going to be resonant. You would do well to anticipate using a tuner.

Hi Steph,

BalUns are passive devices. Any addition of active circuitry will
likely limit their utility rather than enhance them. Perhaps if you
were to describe the purpose or application you seek to accomplish,
then it would aid us.

Hi Scott,

Sounds good right there.

>Even still, I have read that there is capacitive reactance
And perhaps you would find a platinum egg if you killed the goose -
than again perhaps not.

What you read is true, but you have cast some variables into the mix
that seem to balance out to a perfectly useful solution. You could
submerge into the arcane world of antenna academics to find out why.
Or you could discard a working antenna to design the perfect one that
works no better. Or just talk on the radio.

Hi Jerry,

Sounds like another wonderful chance to use your slotted line. When using ferrites to build a choke (the 1:1 BalUn), make sure to select the coax shield at BOTH ends (not the inside lead and coax shield pair) to measure.

The object of your measurement is to maximize Z. Using a short coax lead going through two small beads, you should find a Z that is actually quite close to 50 Ohms - that is, if you have the right ferrite formulation. If you do not, it will be some other value certainly, and not entirely useless (and possibly better).

As you add beads, the Z will add arithmetically - a simple one for one linear increase. This too you can confirm by measurement. If you find a large toroid that you can pass the coax through, the Z will add by the square of the turns (geometric progression). This too you can confirm by measurement.

However, at VHF there is a conflict emerging. You want as many beads as possible such that their Z presents 3 to 10 times the load Z. However, you want to minimize the length of the coax to no more than a twentieth or tenth wavelength long.

Give us some results along the way.

Richard

Yeah, I actually built the line so I could get some *numbers* on the
actual impedances invovled with these VHF loads. It seems to be working
'good enough'. I was surprized (disappointed) last night when I was able
to resonate the coil of coax shield by winding it thru a ferrite toroid and
get only about 300 ohms quite completely reactive.
I have seen baluns made by wrapping coax into a coil, without the ferrite
toroid. They seem to work well. I thought I could miniaturize the balun
thru the inclusion of the ferite core.
Maybe I should make a balun like the ones I read about and measure what
impedance it has.

I consider myself to be so uninformed that I know there are guys reading
this group who know the answers to what I'm trying to learn. So, I thought
I'd cheat and get the answers from you guys.

Note -- I am using only "surplus" ferrites. I have several toroids and
alot of tubes. I assume the tubes are high permeability with lots of loss.
I dont know what the permeabilty of any of these ferrites is.
I wish I had a pattern range big enough for VHF. Maybe I wouldnt have to
ask so many questions.

And, Richard, I'll try sanitizing my set up so I can send you a picture of
the toroid balun I tried to evaluate last night.

| Hi Chris,
|
| Mount a mobile CB antenna to your balcony(?) and put a festive wind
| sock on the end of it. It doesn't have to be strictly vertical; so
| set off at a 30 degree angle would be consistent with the festive
| camouflage. As for "non-inverted" V antennas, I would suppose the
| majority of the CB crowd is vertically polarized and being cross
| polarized with a strict horizontal would conflict with your desires to
| contact friends and family.
|
| You might try with a full wave horizontal or vertical loop. This
| would run roughly along the perimeter of a room at the ceiling or a
| wall. You may just wish to do all walls and the ceiling with an
| antenna switch as this would have distinct nulls. As it is distinctly
| unlikely that you would have 12 foot ceilings, such loops are not
| going to be resonant. You would do well to anticipate using a tuner.

777. Hustler 4BTV / 5BTV with antenna tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-26 19:52:34 UTC
From: waltw@bellsouth.net
Message-ID: <64bea83e.0407261152.36ed905@posting.google.com>
Source record: 91998

Hello everyone!

I wonder if anyone has any experience with this. I operate almost exclusively with a Hustler 5BTV trapped vertical (ground mounted) on 20 meter PSK31. The other night I noticed some activity on 30 meters PSK. Since my vertical cannot operate this band with an acceptable SWR, I'm toying with the idea of running the antenna thru my tuner. However, it seems that a while back, I heard that potential damage can result to the traps, if one attempts to "tune" a trapped antenna.

Has anyone been doing this successfully? For what it's worth, I rarely run more than 25 watts.

Thanks in advance.

Walt KJ4HE

Be careful to the application of the word resonate. Are you being
literal? At VHF it would seem unlikely that coiled coax would need
any ferrite to perform resonance, and hence the warning of
size/length.

> I have seen baluns made by wrapping coax into a coil, without the ferrite
>toroid. They seem to work well.

This is a conventional choke which serves as BalUn.

>I thought I could miniaturize the balun
>thru the inclusion of the ferite core.

Not an unreasonable speculation, but there are different formulations
of ferrite that could aid this, or be as productive as Krispy Kreme
donut.

> Note -- I am using only "surplus" ferrites. I have several toroids and
>alot of tubes. I assume the tubes are high permeability with lots of loss.
>I dont know what the permeabilty of any of these ferrites is.

You have the instrumentation to test all of these possibilities, and
that is miles down this road in your favor. However, I would note
that with BalUns and ferrites applied to them, it is not high
permeability you are seeking. Ferrites for these applications are
purely resistive with a negligible contribution of reactance. The
cores WILL heat up with a resistive loss under certain circumstances.
You should be able to confirm this as well with measurement.

To make it simple:
1. take a short loop of wire;
2. pass it through a test material (be it toroid or tube);
3. connect this loop at the end of your slotted line;
4. measure the characteristic in the r ï¿½j Ohm fashion;
5. repeat 1 - 4 for each remaining item in your stock;
6. report your survey.

Hi Chris,

Use the air conditioner as ground plane (there is nothing sacred about
this function). Tip the antenna out and away from the building to
clear obstructions and nearby conductors (do whatever it takes, how
much choice beyond this do you have anyway?).

Use a tuner - you stand little to lose so don't fight it by taking
stock in myths about "resonant" antennas - no such requirement demands
you observe such oft-repeated mantras.

If you wish to have a hard and fast rule, it is to maximize radiation
resistance and minimize ohmic loss. Radiation resistance is
intimately tied to the size of the loop, radiator, or dipole. Ohmic
loss is found in poor connections and poor materials. If you keep the
radiation resistance high (use standard size antennas) you will
probably not have to worry about material losses (except for corroding
connections).

Now to put a number to radiation resistance to give you some sense of
scale. That 109" whip for CB when mounted to the car bumper exhibits
about 50 Ohms of radiation resistance compared to the bumper's ohmic
loss of 0.1 Ohms (mostly found at the connection). This is a standard
size antenna, or roughly one quarter wave (half wave if you include
the car). If you shrank that down to 12" mini-whip, then you might
find it offers only ï¿½ Ohm radiation resistance, and suddenly the ohmic
loss becomes significant. Making an antenna smaller finds a sudden
plunge into poor efficiency when you get below an eight wave for an
element.

Why is that?

And, do you mean the electrical length of the inside of the coax, or the outside? The velocity factor of the outside is of course highly modified by the presence of the beads, so the electrical length would be a great deal more than the physical length.

Richard

I'm aware that I'm not well informed on most electronics by today's
stamdards. I've been away from the field for too long. But, now i feel
stupid, because I thought the only reason for using the ferrite core was to
introduce permeability.
I recently became aware that alot of ferrite tubing is available where
high loss & high permeability is desired for isolation needs.
I thought it would be easy to introduce enough permeability with a low
loss ferrite toroid core so the number of turns would be reduced.

This "test of ferrites" in my garage is so nonrigorous that the results
dont even count. I concluded, last night, that I need help. One problem is
the losses in the high permeability ferrite lowers the Q of the inductor so
the loaded cil Zmax is actually fairly low. I was able to get the highest
Zmax with the coax wound thru a toroid ferrite whoes permeability wasnt
aparently very high. And, I think there is a significant amount of
radiation from 1 inch diameter coils at 137 MHz. That forces me to think
while I'm trying to understand what I'm doing.

I have been thinking "resonance" when this 'coil' is purely reactive.
I'd have absolutely no reason to state that I'm using the right word.

Hi Jerry,

Think about this statement above.

If there are loses, then you have resistance. QED

You might want to maximize X (and Z necessarily follows in increase),
but R will do the same job (and Z necessarily follows in increase).

I want to see some data:
>>1. take a short loop of wire;
>>2. pass it through a test material (be it toroid or tube);
>>3. connect this loop at the end of your slotted line;
>>4. measure the characteristic in the r ï¿½j Ohm fashion;

>>6. report your survey.

As a reference, do the same steps 1 - 4 with JUST the wire loop. This
is a simple test of your hypotheses and removes it from the "guess"
column.

Howdy,

While operating "mobile" in a campground I attached a Hustler mast to the frame of my trailer and used the 20-m resonator to operate on 20. I also ran a random length of wire about 20 feet up a 33-ft MFJ fiberglass telescoping pole then horizontal to a convenient tree to use on for 3.91 MHz nets. This formed an inverted-L. The wire was connected to the upper end of the Hustler mast and the resonator was removed.

I tuned the wire for 75 m with an MFJ tuner. Then I wondered what wud happen if I connected the wire to the upper end of the 20-m resonator while it was in place..

I tried it and the combination was resonant very near 3.9 MHz. (Happy accident!)

The internal AT in the rig wasn't needed, nor was the external one. Two days of rain in the campground prevented me from trying various combinations of resonator and wire length.

Anyway, I think it’s interesting.

Walt,

You are correct in remembering that damage can occur to the traps. The manufacturer *specifically* warns against using a tuner to try to "stretch" the 4/5BTV to bands for which it wasn't designed.

As for at what (low) power you might be able to "safely" get away with it, I don't know ... I have not even tried using my FT-817 (5W) into the 5BTV with the Z-11 autotuner, having had the finals fail catastrophically once for NO reason (no bad load, no overvoltage, nothing ...) Fortunately, since the finals were replaced, the 817 is good as new and I want to keep it that way :-)

You could always consider hanging a simple wire dipole or a random wire with a tuner for 30m if you just want to operate PSK casually.

73,
Carl - wk3c

Richard

I did try compiling some data for you, doing it "your way" and, in the process, thought my measuring system was faulty. So, I added an RF amplifier to the probe outlet. The additional gain in the system seems to make the home made balun look real good.
It becomes apparent that I need alot of help. I'm sure glad that you've taken time to get me thinking straight.

Jerry

Interesting question Roy since the electrical length of corregated hardline
coax
could be aproximated as twice the physical length of the inner conductor !
I wonder if the corregations affect things both underneath the beadings and
away from the beadings?

|> Jerry
|
|Hi Jerry,
|
|Sounds like another wonderful chance to use your slotted line. When
|using ferrites to build a choke (the 1:1 BalUn), make sure to select
|the coax shield at BOTH ends (not the inside lead and coax shield
|pair) to measure.
|
|The object of your measurement is to maximize Z. Using a short coax
|lead going through two small beads, you should find a Z that is
|actually quite close to 50 Ohms - that is, if you have the right
|ferrite formulation. If you do not, it will be some other value
|certainly, and not entirely useless (and possibly better).

Yes, if it's not 50 it will be something else [g]. It is to be hoped
that it will much greater than 50.

|
|As you add beads, the Z will add arithmetically - a simple one for one
|linear increase. This too you can confirm by measurement. If you
|find a large toroid that you can pass the coax through, the Z will add
|by the square of the turns (geometric progression). This too you can
|confirm by measurement.

|
|However, at VHF there is a conflict emerging. You want as many beads
|as possible such that their Z presents 3 to 10 times the load Z.
|However, you want to minimize the length of the coax to no more than a
|twentieth or tenth wavelength long.

I hope by the last you mean the length needs to be minimized while making the measurements and not in the application. I would just as soon have my 200' of Heliax ferrite loaded all the way from the antenna to the shack.

Regards,

Wes

Well, I didn't get to do any transmitting tests but on the receive side, the V antenna was much better than the mag mount antenna on the A/C. That antenna is a 4 ft. base-loaded, shunt-fed Antenna Specialists unit. I haven't tried bending it outward yet. Both antennas have less than a 1.5:1 SWR.

796. Wire antenna question...

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-27 05:33:04 UTC
From: Dave <Devarim@hotmail.com>
Message-ID: <07d76cdbe4cd9bd72438dabe1c3456f8@news.meganetnews.com>
Source record: 92017

I'm moving to a new house - it's big, on a big lot. But there are no options for a 'proper' antenna that my wife and the neighbors would agree to. So what I want to do is run a wire from the top of the house connected to a pole 10 feet above the roof to a fence at the far end of the yard. Quite hard to see, and long. Easily well over 100 feet - perhaps
more (haven't closed on the home yet, so haven't measured). The high end will be about 35 feet up, sloping down to the fence
to a pole on the fence which will put the end at about 10 feet.

Question: Is there some 'magic' length that will be the easiest to tune with my Kenwood 180-series manual tuner? I would like to work 160 thru 10, but will live with less. Are some lengths of 'random wire' antennas better than others?

Question: the 'feeder' will of course also simply be wire. I plan to run it down the side of the house in 'TV' twinlead insulators screwed into the siding, and then through a 'TV feedthrough' tube into the garage (in my whole life, my ham shack has NEVER been relegated to the GARAGE!!!) Will this be ok? I don't use an amplifier - 100 watts max - the wire would pop through the garage wall and right into the tuner...

Thanks for any input,

Dave WB7AWK

Harold

Would you consider the Log Periodic Vee antenna design??

I like it because it covers the TV bands so well. The longest elements
radiate as 1/2 wave dipoles at the low end (2 thru 6) and then again as 3/2
wave dipoles at the upper bands (7 thru 13).

As I see it, the "Ving" of the 1/2 wave elements doesnt alter its
radiation pattern excessively. But, when it radiates as a 3/2 wave length
antenna, the lobes from each half of each element are positioned by the V
angle to add in the forward direction.

Jerry

I hope that was obvious by follow-up questions - viz. the short loop
of wire described in the measurements.

Further, if there are a number of beads to add, having them spread
along a full wavelength would not seem as beneficial as within a tight
group. If that tight group were remote from the feedpoint, it would
also suggest that the distance would offer a means to drive the
intervening section into radiation.

If you or Roy have conflicting data to this surmise, now is the time
to reveal it. That is, if there is no need to regard grouping, please
provide context. In other words how much isolation is provided with,
say, 20 beads spread over a quarter wave instead of a twentieth wave.
Further, how much isolation is provided with, say, 20 beads located
half a wave away from the fed end in contrast to within a twentieth
wave of the fed end.

Got lucky first try...:) I use that method to tune 160m on mine
sometimes. "using an 80m coil" One nice part is the antenna will
usually be more efficient than a normal length mobile whip. Less coil
used with the extra capacitive loading. Had a friend of mine that was
down near Corpus Christi on a vacation, and was working him mobile on
40m. The band fell out, and we needed to go to 80m, but he didn't have
the antenna. I just told him to tack a wire onto what he had and go
with it. Which he did in the motel parking lot. I think he ran the
wire to a small tree. Worked great. The only thing to avoid is having
the wire real near the car body for any large distance. Bad news...
But take it away from the car towards another support like a tree or
mast, and it works fine. MK

Hi, Richard !

Well, I'm sorry if I made a mistake but I've found in a thesis,
circuits that are for active baluns, using FET:
http://www.unilim.fr/theses/2003/sciences/2003limo0028/images/image251.gif
a) Long-tail pair b) Common Source-Common Gate c) Three transistors
It is true that their use introduce many problems, such as complexity
in stability and linearity. Moreover, an active balun is unilateral.

Well, my problem is to simulate with a software like Cadence some
circuits and to compare results obtained with another software called
ADS: ADS stands baluns, but Cadence don't. And I'm trying to find an
easy balun circuit, well designed, that would make both results
converging...

I hope It's a bit more clear :)
Thanks in advance

Steph

Richard

Where do I start yet be brief?? What can I offer as data?

At 137.50 MHz, I can measure nulls as low as 260 to 1 with a short on the end of the Slotted Line.

The two directional couplers I'm using indicate that the return voltage from the Slotted Line when loaded with a coaxial 50 ohm BNC load is 0.05 volts when the forward voltage is 1.00 volt.

I made an attempt to make a balun by winding 4 turns of RG223 coax thru a pair of ferrite toroid cores. I connected the outer conductor at each end of the coil to the Slotted Line and measured a VSWR of 40 with the null shifting 1/4 wave from the null location with a short. That implies that the "balun" has a very high impedance to a 137.50 MHz signal. I put that balun on the dipole array in the back yard and will try it tomorrow. So, I cant re-measure it right now. I did take pictures of the coil and toroid.

I made a second "?balun?" trying to use a bigger toroid so only one toroid with more turns might be considered. The VSWR with that (bigger) toroid was slightly less than 5:1 and the null moved only 0.24 lambda (toward the input end of the Line). So this bigger toroid ?balun? provides an impedance of around 225-j50 to the signals on the outside of the coax.

Next, I'll try to evaluate a balun made with sub miniature coax wound around a small ferrite toroid.

Hi Dave,

I have in the past used several wire antennas such as you discribe. You did not say in your post what your major activity will be DX , Rag Chew , Etc. In any event 100 + feet is good choice.. I've used a 90' foot sloping wire here many times with good results. you will need a good R.F. ground /radial system. doubt at 100 feet that your tuner is going to let it work for you on 160m but then i'm not familar with at tuner.

If I were going to do it again the way you say I would invest in a SGC smarttuner and feed coax to the tuner outside the shack.

Now as to the radiation pattern-- unfortunately a sloping wire such as you discribe will tend to give you high angle radiation patern on the hight freq. (Actually lower Freq. /but that's another whole story) say above 30m the major lobe will tend to be higher than optimal for good dx but it should still produce qsos. You might want to check out Cebiks

excellant work on Inverted L's that will give you some Ideas of what to expect. Although each sight is different.

Hi Steph,
Baluns are NOT always passive devices- it is quite common to find active
baluns in both the space and consumer industry. Winegard antennas used to
produce a very low noise MATV preamplifier whose input was an active balun-
thus dispensing with the loss associated with a passive balun.
I encourage your interest and research.

Hi Dave,

The longest is the wire the easier you will tune it to a low SWR and could radiate enough power into space.
I worked longtimes with simple longwire 20 and 40 m long (60-120') placed outdoors at 4-5m (~12 ft) high only, with a 31m (102') G5RV placed at the same height (a bad day for the ladder line that touched the grass or rather a small bush 30 cm high, Hi) and with sloper 20m long fixed on the house concrete wall.
Those antennas allowed me to work perfectly locally (bordering countries and all through Europe, this in a radius over 2200 km) as well as DX stations from ON to K, PY, 9K, 4S, UA9, HS but not up to 10000 km away. HS is close to but I never did many such DX with these wires placed so low over the ground. Why ? Due to their poor radiation pattern biaised by the ground influence.

My only error was to use the sloper without balancing the impedance and I never get a low SWR to the antenna and thus I transmitted with as low as 10 W over my 100 W PEP !

About my longwires (flat-top or almost) they where simply tight over the garden and connected to the transceiver without balun and open-wire/coax like there were on the dipole. So I radiated a lot up to into the shack (with 100 W PEP, I reached to output 60 W anyway), the wire arriving by the window (at 2m high over ground) and having only 50cm to 1m to run indoors to reach the RTX).

Of course any tuner will help you to get a low SWR and to balance the impedance to 50 ohms.
On 160 and 80 m this is another affair, and mainly for the lowest band. But try, this is the objective in being amateur radio too...

But if you haven't buy it yet, first of all install an external SWR-meter to know exactly what amount of power reach your antenna as your internal RTX meter gives you only its own SWR, not the one going to the antenna... There is a world apart : you can get SWR 1:1 at the TX output but SWR infinite at the antenna input too !. That mean that reading SWR 1:1 on the RTX you beleive that you transmit at 100 W PEP but all this power is lost as heat ; you will shout and shout at the mike without working the least station because your SWR at the antenna is sky high... too pity, and better to know it before speaking at the mike ;-)

To begin, you will find more info about wire antennas here :
http://www.astrosurf.com/lombry/antenna.htm
http://www.astrosurf.com/lombry/qsl-longwire.htm

About SWR:
http://www.astrosurf.com/lombry/qsl-swr.htm
http://www.astrosurf.com/lombry/qsl-transmission-line2.htm

> Question: the 'feeder' will of course also simply be wire. I plan to run it

Not sure at all that the feeder made of your simple wire will not pickup RFI from any conducteur longer than 1/4-lamda place in your garage or anywhere else. In using an open-wire (to maintain outdoor and without touching the ground) or a coax (a bit more lossy) you will prevent this problem and can balance your impedance to adapt to the one of the RTX.

My advice : buy some tens of meters of ladder line and RG58/U coax and made some tests. You will learn a lot of things.

Buy or read also the last edition of the ARRL Antenna Book (now it comes with a CD where files are saved in PDF) or any other about wire antennas published by ARRL or RSGB. There are a lot of readings on these matters too.

Hope this helps.

ah. that's why they always say "think before you post". i'm guessing the original author probably meant meters instead of megahertz...right, Paul? ;)

my bad.

813. feed line and coax : longwire vs dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-27 15:46:11 UTC
From: Thierry <"to answer direct see http">
Message-ID: <410678c4$1@news.vo.lu>
Source record: 91933

Hi,

I want to tight a straight 100m (300 ft) or 2x50m (in horizontal V) longwire over my garden probably at a height close to 10m, not more.
I like this design because in using very long wire (3-5 lambda or more), its radiation patterns (Az, El.) show more lobes with a low takeoff angles than a dipole.
My question deals with the matching section.
Do you confirm that the next design 'd work fine (this is for DXing) but the problem is purely technical ?

From the centre part of the longwire (at about 50m that will be cut) I'd like to use a lambda/4 feed line or so (a open-wire of 600 ohms close to 10 m long)
It will run vertically down to the ground.
I will not use a balun 6 or 4:1 after the open-wire.
From this point 10m away, I use a RG58 or 213 coax to the RTX.

But here is my question, does it means that one segment of my longwire must be soldered to the braid of my coax, the other one at centre of the coax ?
Does this design transform my longwire in dipole ? I believe...

Or is there another way to link the ladder line to the coax (or using no coax at all to the RTX, I don't think so), without transforming this design in dipole and keep what I 'd call the "longwire properties" ?

Thanks in advance

==========

You will have an inverted-L antenna. With the down-lead overall length will be of the order of 130 feet, or a nice 1/4-wave on 160m.

Actually, on 160m, a nicer length is roughly 150 feet. This is because 150 feet is very easy to tune up. Perhaps you could make an inverted-U out of it. It may need only a 500 pf, relatively low voltage tuning capacitor in series with the near end of the wire. The longer the wire the smaller the capacitor setting.

The antenna will work quite well on all HF bands with a tuner. But performance will fall off relative to a 1/2-wave dipole cut for a particular higher frequency band such as 10 or 20m. For practical purposes, taking one band with another, it can be considered omni-directional. Use thin 18 or 16 gauge, unobtrusive enamelled copper magnet wire.

You will need only a modest ground system such as a few (6 or more) shallow buried radial wires extending in various directions, of various lengths, from one wall of the house into garden soil. On 160m, radial wires only 20 or 25 feet long will be quite effective. In dry stoney soil more ground wires may be useful but not necessarily any longer.

Also make use of the domestic hot or cold plumbing system. The transmitter will pick up yet another ground via its power line connection. But don't even think about a ground rod - it will be useless - hardly better than one radial of the same length.

Dunno about 4BVT but my child bride retuned her Butternut after a heavy rain, made several quick contacts then cranked on her amp to reach a friend and promptly blew her finals. The SWR had shot up! I attributed it to water in the caps being boiled off by "them killer watts" but who knows. I "KISSed" the problem away by selling the 'nut and putting up a set of wire dipoles that work even better than the 'nut did.

This is data! It tells me that your system is capable of measuring
over a considerable range of SWR.

What do you measure with an open?

> The two directional couplers I'm using indicate that the return voltage

What does the slotted line ITSELF measure?

Low SWRs may be more difficult to measure because of your limited
resolution (as distinct from considerable range shown above). Here,
it makes sense to measure NOT the DC voltage of a detector, but a 1KHz
modulation using a specialized VTVM designed for this purpose. It
includes 1KHz tuning to keep out noise, and a stepped attenuator to
allow for exaggerated and sensitive scaling. The wide meter scales
are perfect for low SWR, and the stepped attenuator takes care of
extreme ranges of high SWR.

THIS is data!

Hi Jerry,

The first BalUn with a SWR of 40 tells you that you have a superlative
example of material for your application.

The second BalUn with a SWR of more turns with a SWR of 5 is simply pitiful in comparison. It is useful as a minimum value and suggests the material in this ferrite is mediocre for VHF (but may well shine in the HF).

I don't think such an antenna exists. Mobile HF antennas are physically shortened, with loading coils or resonators, and by nature have a narrow bandwidth. To cover the frequencies you mentioned, some tuning is going to be required for greater bandwidth.... either an antenna tuner at the rig, near the antenna, or built-in to the antenna (such as the "screwdriver" types). You could use the economical Hustler mobile antenna system with the multi resonator adapter, which allows for up to 4 bands to be use (I think), but even then, each resonator is going to have only a certain bandwidth, and to go from the CW portion of the band to the SSB portion may require adjusting the tip on the end of the resonator. Not to mention the whole thing would be seriously gawdy looking. Icom and Yeasu both make remote tunable mobile antennas, but like the screw-driver types, they can be pricey. I would home brew an "Outbacker" type of antenna and just change the fly lead connection when you want to change bands.... There are websites that show how to build them using various materials.

>converging...

Hi Steph,

Well, what you show above are inverters and buffers. They can
isolate, and they can invert, and I suppose they can act as
substitutes for a BalUn, but simulation software should have some
capacity to offer "perfect" transformers that would do just as well.
Or such has been my experience.

However, this says nothing of the APPLICATION which may suffer
comparisons where you lose significant characteristics - unilateral
response being very significant, or insignificant depends entirely on
APPLICATION.

You originally asked for "schemes or plans to design an active balun"
and you offer exactly this in your link above. What is it you need?
Part numbers? What frequency are you doing this at? What drive
levels are going in? What output levels are expected? How much phase
distortion is allowed?

When I look at Cadence's own RF Library, it quite clearly shows
BalUns:
http://www.cadence.com/whitepapers/rf_behavioral.pdf
so it would appear your's is a problem of RTMFM.

822. Does external antenna negate the built in

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-27 19:32:04 UTC
From: James <jrapier@dcr.net>
Message-ID: <W4yNc.40$79.39@fe39.usenetserver.com>
Source record: 91942

I recently bought a Tecsun BCL 2000, clone of a Grundig S350. I noticed that using an external antenna on medium wave seems to leave the built in one still active. Rotating the radio itself seems to change the signal strength.

The radio is manual tuning only with no presets but seems to be a very good box. As you might tell, I am a novice at this and didn't plunge into big bucks on a radio before checking my interests. I did put up a long wire antenna (about 70 feet) and jammed a very thick copper wire into the ground like a wicket about 18 inches for the ground.

The radio works well but I was under the impression that the built in would not be active on medium wave when external is used. Apparently I'm wrong as the external input is just a wire lock arrangement and not a jacked input. This brings up another question. I have a radio shack longwire antenna in a wind up case for use indoors where the outside antenna is not practical. It's 23 feet long and used for extending the whip for FM and shortwave. So is the whip active as well as the built in for medium wave?

Any insight on the arrangement of these things would be appreciated.

Richard

The VSWR with the line open is about 19:1. It doesnt matter if the line has either N or BNC at its output end, opened.

As you know, I dont have a lab where I have access to any standards. I'm using old "swap meet" test equipment and some parts I pulled out of a dumpster. I only waned to build something that would tell me aproximately what the impedance of an unknown load is at 137 Mhz. I think this piece of plumbing pipe does exactly what I wanted.

At 137.50 MHz, I measure an incident voltage of 0.3 volts and a reflected voltage of 0.02 volts into the Slotted Line with a 50 ohm load on its output end. I dont see any variation in reflected voltage when I move the probe or even remove it. The needle does wiggle a few degrees when the probe is moved but that isnt measurable. I dont even know how good this Slotted Line needs to be. I just thought I'd build one since I'm too dumb to understand any other way to measure impedance without buying something designed for the application. Buying things takes most of the fun out of a project.

I could easily have major inaccuracies in this Line and just dont know it yet. But, so far, this Home Depot pipe seems to be able to tell me alot about impedance of unknown loads.

You introduce the possibility of measuring impedances with low VSWR. That has become kinda interesting to me since I've been reading about what people are doing with lengths of coax. Atthough I have no need for determining load impedances with VSWR less than 1.5:1, it might be fun to try to build something. So far, I cant understand how to measure load impedance accurately when the VSWR is under 1.5:1

Hi Jerry,

Opens are generally a little more difficult to nail down.

However, as to measuring very high SWRs, you probably have a fair
amount of error hidden in these determinations. When measuring high
SWRs the problem of measuring the minima often leads to inserting the
probe too deep into the trough to find the null. This deep insertion
will disturb the real SWR and give you an apparent SWR. There are
methods to recover the accuracy, but it is hardly an issue for your
purposes, so I will not pursue that here.

>I think this piece of
>plumbing pipe does exactly what I wanted.

I would agree.

This is not what I meant by reading the matched SWR with the Line.
USE the line to measure the variation along its length. DO NOT use
the arrangement of directional couplers as you have above.

>The needle does wiggle a few degrees when the
>probe is moved but that isnt measurable.

My guess is that you will see very little variation along the length
of the line. Can you confirm or negate this expectation?

>I dont even know how good this Slotted Line needs to be.

As accurate as you need for your measurement - that is, no or little
residual SWR. Judging by your comments, you have obtained this. What
I keep harping on about is the cold facts of data to remove qualifying
statements. You have provided some of the Cardinal measuring points -
e.g. Open/Short/50 Ohm load.

> I could easily have major inaccuracies in this Line and just dont know it
>yet.

Your doubt is unwarranted.

> You introduce the possibility of measuring impedances with low VSWR. That

>load impedances with VSWR less than 1.5:1, it might be fun to try to build
>something. So far, I cant understand how to measure load impedance
>accurately when the VSWR is under 1.5:1

That is because of the sensitivity problem I have written about. You
have great range measurements, but that is unnaturally forced.

***** This is your next step, if you skip it, you will find ***
***** yourself spinning your wheels with muddled results. ***

Build your own 1.1:1 standard and try to measure it - this should be
telling. It will test your skill more than the line (which appears to
be fine), but so much of measurement at this stage is necessary skill.
If you encounter difficulty it is NOT the line! Your limiting
consideration is found at the detector and being able to resolve very
small differences.

Trying to do this with DC measurements from a detector is going to be
extremely hard. You should instead re-read my comments about AC
detectors and 1KHz meters because they are very useful for doing what
you plan to do. I know you may not have access to this specialized
gear, but invention "used" to be part of the craft of Ham radio
(instead of pushing credit cards across display cases).

You can use a spare receiver (it will have to be an AM VHF rig without
AVC/AGC) in place of the detector. Use an AC meter across the speaker
and go to town, you will have all the sensitivity in the world, and
your meter should solve the resolution problem.

>From the cable TV company's garbage pile, one has access to tons of 75
>ohm line. But one wants to make a 40 meter long 50 ohm cable. Ideas?

The Zo of coaxial cable is determined primarily by the ratio of the diameter of the inner conductor to the diameter of the outer conductor (shield). Not much you can do to modify either dimension on a 40m long 75 ohm cable. Depending on the application, 75 ohm cable can be used in a 50 ohm Amateur system without too much of a problem.
If you want to have everything matched, put a matching network at the antenna to match its impedance to 75 ohms. At the other end of your 40m 75 ohm cable, the impedance will be 75 ohms, transform that to 50 ohms with a matching network and you are all set. By the time you go through all that, you may decide it's cheaper and easier to buy 40m of 50 ohm coax.

75 ohm cable is a better match to the centre of a dipole (abount 70-ohms)
than 50-ohm cable. As JGBOYLES sez, it doesn't matter much either way.

To transform 75-ohm cable to 50-ohm requires melting down to basics and
starting again from the raw materials. Or which leg are you pulling?

Reg, G4FGQ

> Any thoughts on this.

What you are contemplating will certainly work on 40m-10m, and possibly 80m. The auto tuners I have looked into use an L network, with the inductor and capacitor values in a binary sequence so you can get smooth matching in 256 or 512 increments. Also the L network topology can be changed, depending on the impedance it is trying to match. You will have to configure your rotary switch, diode encoder arrangment to get the maximum versatility. (this may take some time)
You will also need some sort of match indicator. I use an MFJ antenna analyzer since it has its own signal source. You could use low power rig and swr bridge. And, of course the ground system is important in any vertical radiator system.

You can "EASILY" fill the space inside that *air* dielectric 75 ohm line
with polyethtlene. That will make it close to 50 ohms.
Somethime is is easier to use a coax line 'as is'.

A differential amplifier will accept balanced inputs and generate an unbalanced output. [BAL-UN]

Similarly a any FET can accept an unbalanced input at the gate and if the loads in the source and drain are the same you will get balanced outputs. [UN-BAL]

Choose your active circuit depending on which conversion you want. Then choose components to meet your needs.

Note: These are low level circuits not intended for significant power.

I just bought a Terk Advantage antenna. It really does help my cheap little table top radio get stations a lot farther away. Will I still be able to use it when digital AM radio arrives?

Well Paul, below 30 MHz is NOT CB radio. If you operate there and FCC finds you, you will face very stiff fines up to $10,000.

CB radio is confined to 40 specific channels in the 27 to 27.5 MHz frequency range.

Be careful!!

paul wrote:

|From the cable TV company's garbage pile, one has access to tons of 75
|ohm line. But one wants to make a 40 meter long 50 ohm cable. Ideas?

Ideas:

1) Use as is. At h-f this is a viable solution.

2) For single-band use, there are any number of ways to match each
end to 50-ohm. You could stub match at each end, use geometric mean
1/4 wavelength line sections at each end, or series-section
(alternating 50 and 75 ohm sections) at each end.

3) At h-f, you could use wound broadband transformers.

4) Don't use it at all. "Free" isn't necessarily free after you
factor in the expense of doing the matching and fabricating one-off
connectors. A 125' length of decent coax isn't that expensive.

I dont have the Antenna Handbook. But, is that the trifilar wound 1:1 balun?? I have tried several trifilar baluns but always get too much insertion loss. I think a good trifilar-ferrite-1:1 balun would be exactly what I'd like to be able to make.
I suspect the 1/2 wave bakun you refer to is a 4:1 impedance transformer. I want to get a 1:1 balun.
The coax in the ferrite toroid is desireable because it has low insertion loss. I am certainly not an expert on baluns.

The line is 5 feet long where it is 2 inch ID (the transitions to N
connector contribute another 6 inches to the line length). The slot is 4
1/2 feet long. If the probe is restricted to the center 4 feet and the
probe is "slid" along the track, the voltage output from the probe varies
by about 1/4 of one percent with the little BNC 50 ohm load terminating the
Slotted Line.
You are doing a good job of getting me to think. I really dont know what
I'm doing. I just did it, thinking a crude line like this would provide
decent estimates of the load impedance.

I wish I had some *known mismatches* for a 50 ohm line. I may be kidding
myself when I measure the loads I've choosen.

Thanks for doing the thinking for me.

Hi Jerry,

Sounds like just what it should do if you built it right. You've done
this several different ways so trust your work.

> You are doing a good job of getting me to think. I really dont know what
>I'm doing. I just did it, thinking a crude line like this would provide
>decent estimates of the load impedance.

It will. You now only have to increase the skill to measure a
"useful" Z rather than the absurd situations of short or open. They
were OK for a sanity check, but you really need to test the line WHERE
IT IS GOING TO WORK! That is, in the 1.1:1 to 3:1 SWR region.

This requires you make your own calibrated mismatches.
>
> I wish I had some *known mismatches* for a 50 ohm line. I may be kidding
>myself when I measure the loads I've choosen.

Enough already. You have them, you are simply not using them. I
would bet dollars to donuts you have a T connector. connect it to the
end of the line and then connect two 50 Ohm loads. BINGO! Instant
2:1 SWR mismatch load. That will give you 25 Ohms, find some way to
put the two 50 Ohm loads in series for another mismatch standard.

Go to Radio Shack and make the cheapest purchase of precision you can
afford: a range of flea-sized surface mount resistors and surface
mount capacitors. Buy several male BNC connectors and start
soldering. Another source of good 50 Ohm loads is found in Network
terminations already built into BNC connections. These suckers are
good and accurate and a drug on the market. If you couldn't find a
way to parallel 2, 3, 4, or 5 of them, you aren't trying very hard.
These all present perfectly good mismatch standards if you keep

connections short and equal. Again, this involves the one-twentieth wavelength rule (I note there has been no conflicting data from others to perturb this).

Hmm, I had a 40m switching diode fail short which took out rcv on 6m
(7th harmonic), but nothing like your problem. I believe mine had to do
with very high RF fields from 6m during a June VHF QSO party.

I also run a Z11 into a Gap, and use it a lot to match to 30 and 17.
What were the circumstances when the finals failed? Sounds like you
were running into a good load, but you didn't quite say that.

Pretty much agree with Jack-- the only tuner that was automatic, and
designed to withstand VERY high impedence mis-matchs was the Heathkit
(even kw rated, to longwire if memory serve correct) and these ain't
dainty! The new breed of them Yaesu, Kenwood, Icom, ect that matched the
rigs , are designed for (in their spec books), a maximum of 3:1 swr
(and this at 100 watts)! tho, in truth, will handle wider range, above
5-6: to 1, usually start arcing because of the flakey impedence shifts!
Must admit, to all, that these probably more suited to tune the input
for an AMP, than a useful antenna matcher!

Ye-Gads! Why so Complicated?? and, Complex? wouldn't a bandwidth of aprox. 6 MHz be sufficient? And, why, pray, so LONG? for 137.5 MHz center?? in short, whats the matter with a Sleeve- 1/4 wave length long CHOKE BALUN ? These are quite easy to construct from copper tubeing, and wire (KLM antennas did these for years for 2 meter, and up yagis), and can easily change impedence for , say 50- 72 ohm matching (simply convert the base impedence to 61.23 ohm impedence- the length stays the same!
For reference, look for an article from QST called the "BEER CAN BALUN" altho, sadly, beer cans are no longer made of steel, and openable at both ends with a can opener!(so they could be soldered to), but, that does NOT NEGATE THE THEORY INVOLVED!! One simply constructs the COAX, with a torch, and then, AT ONE END, 1/4 wave down the section, SOLDER A third, larger diameter piece of copper tubeing to ON END of the recently made coax! If more bandwidth is needed, would expect that ferrite (for the want of better word "beads", the size of the outter shieth of coax, be stacked end to end for about 25-30 inchs, on your coax . For your consideration- Jim NN7K

>Ye-Gads! Why so Complicated?? and, Complex?

Hi Jim,

This is not about BalUns. This recent round of correspondence relates
to one style of BalUn that is easily constructed to offer a means to
test Jerry's SWR bench. He already has a very good BalUn built,
tested, and in service.

73's

OLD tech here..

The original RCA Theremins used a large antenna coil below the antenna, to make the instrument more playable. Unfortunately, not much information remains, especially exactly what the theory was behind their selection of values.

http://home.att.net/~theremin1/RCA/rca_theremin.html

At 200kHz, were these antenna coils at self resonance? Near? If so, how far away?

I'm looking to translate this to a 750-800kHz design, but I'm not sure how to design the coils.
I'm considering winding the coils by putting down two strands of modern magnet wire, on lexan forms, then removing one strand, getting roughly the same winding pitch and Q as the originals.

The two antennas will feed a repeater that will have its own antenna (well seperated) so no cavities will be needed.

I did do some search on stacking antennas with very little help (believe it or not). I did find a few sites with help, but I also thought I would would get a second opinion here.

Jim, used very tenderly (no more than 500w), the new MFJ-994 is a good performer so far. Likewise the MFJ-993 works well at 125w. I have used both on a dipole and voltage-fed longwire. On the dipole, it flattens the once perfect-resonance but stretched from age swr back into1:1 again, and works well and fast on frequencies several bands above. Before those ATU's I was quite pleased with the MFJ-962D at 1,000w it has never arced before.

James, if your radio is similar to the Grundig YB PE400, yes. I always
collapsed and stowed the whip antenna when using an external, either inside
retractable wire or external long wire. Otherwise, moving or bumping the
radio tended to craete static when the whip was touched or moved.

Sorry, I had missed that context. I completely agree with your advice that this length be kept short. There should be no limit on the length of the wire used for the finished (1:1) balun, and I now understand that you didn't intend to imply that there was.

There are two ways current can be caused to flow on the outside of a feedline, by conduction and by coupling. An example of pure conduction is a dipole fed with a symmetrically placed coax line. In that case, the conduction is prevented by putting a balun at the antenna feedpoint. But current due to coupling can be more difficult to suppress, since the balun guarantees only that the current at the position of the balun will be low. In some cases, all it accomplishes is to move the current maximum to a different part of the line; in others, it ends up suppressing the current on the entire line. A method that insures suppression is to put baluns about every quarter wavelength, since no substantial current distribution can exist with a forced node at this interval. However, that's usually overkill, and a single balun is often sufficient. The optimum position, however, has to be determined for the

individual case by modeling or experimentation.

I don't know of any work that's been done on comparing various balun distribution schemes, and the results would be interesting. It does seem to me, though, that you wouldn't want to space moderately resistive beads along a line, since this could result in significant loss. From that standpoint, it would be best to have localized regions of high resistance.

No. The whip antenna is for shortwave and FM. There is a built-in ferrite antenna for medium wave and external connection for AM/shortwave. After pondering over it I think the whip and the ferrite are both active at the same time as well as any external.

Hi Dave,

I guess I will bite here.

This is a curious work from the museum of tubes. In glancing around
the page I note there is actually a lot of symmetry of design,
especially with the oscillators. I also note that there are some
missing component values, for instance, and notably, C11 and C12.

Through symmetry, it is also apparent that the reference oscillator
cap, C16, is mimicked by the T9 antenna loading circuit. I say this
because the pitch variable oscillator has no cap that corresponds, but
the function of fine frequency control is obviously practiced here.

Reading about the Volume Circuit and viewing its design, we also see a
symmetry here too. However, the discussion of T3 and T9 "resonances"
are something of stretch (having nothing to do with oscillation), but
useful as a metaphor. The function of either of these circuits is to
aid in the hand's capacitance in "pulling" loads.

As for your question about quadrupling the frequencies involved, I
would echo: Why?

There are any number of issues that would need to be balanced here,
and they all start with the hand capacitance which, presumably,
remains the same over the ages. There is the mechanism of pulling and

plate resistance coupled with these loads and their Z. If you shift the load Z by making smaller inductances (which follows from the reduction of the coil to attend the increase in frequency) you then shift the load line. This could make for a very difficult to control Theremin where the hand movements are too very close, or are forced to be much closer (depending upon the new dynamics introduced) compared to former operation. Same thing goes if you choose to reduce the capacitances of the frequency determining capacitors in the oscillators; then the hand capacitance becomes more significant and range changes become greater (the Theremin is more sensitive).

Throughout, I was presuming you have access to tubes as specified. For much of the circuitry, this is not too demanding (modern twin triodes would probably work as well). However, when we get to the Volume control circuit, you definitely need power transfer to light up the filament of V5 and its transconductance properties are intimately tied into the successful operation. This means V6 cannot slouch in the power department. The reference and pitch oscillators, and the mixer are pretty conventional as is the AF power amp.

Returning to the question of coil construction. There is nothing sacred there. I wouldn't worry about Q because one wire diameter pitch is not the best (3 is better) so the original designers didn't really care either. As for resonance, these circuits are swamped by 2200pF, interwinding capacitance hardly enters into the picture. If they are resonant, they are series resonant.

|individual case by modeling or experimentation.

I did put together a simple model and pretty much satisfied myself
that it can be done by modeling, although, I've got better things to
do right now.

The model can be a simple horizontal free-space dipole with an
additional wire normal to the dipole connected to one side of the
feedpoint. (I believe this is your idea) A short (one-segment) wire
contains the source, a pair of wires comprise the dipole and a fourth,
variable length wire represents the "coax".

Loads can be placed on the "coax" of various impedances and positions.
Looking at the vertical E field response gives a measure of the
suppression of radiation from the "coax". Of course in this case it
appears that having the load at the feedpoint is optimum as expected.

While I didn't explore it further, I believe that if the "coax" angle
with respect to the dipole is changed to other than 90 degrees, and
the length is fiddled with, coupling will result and then other load
positions might be more effective in suppressing unwanted radiation.

|
|I don't know of any work that's been done on comparing various balun
|distribution schemes, and the results would be interesting. It does seem
|to me, though, that you wouldn't want to space moderately resistive
|beads along a line, since this could result in significant loss. From
|that standpoint, it would be best to have localized regions of high
|resistance.

This is confusing to me. Isn't "loss" what we're after with a balun?
And if suppression of effects of coupling to the line is the goal over
considerable bandwidth then I suggest that distributed loss might be
the way to go. Thus my slightly tongue-in-cheek comment about loading
the whole length of coax with ferrite.

Regards,

Wes

Hi Wes,

I have built one (not difficult, obviously), but testing is a bit less
conclusive. All I can say is that it didn't hurt. I anticipated
using it where the line might upset fields and affect lobe
performance. I also used it in combination with the standard one foot
long design. However, having said that, I only used it in field day
set-ups where no antenna was particularly hi-tuned.

Wes

Let me begin by identifying myself. I'm an old guy who doesnt know much
about current electronic technology. I'm just having fun with this project

of making a home made antenna that isnt expected to perform as well as designs that are already available.

I thought the loss in the dissipative ferrite tubes slipped over the coax's outer conductor might absorb some "power", and thereby introduce an overall insertion loss.

If I was adequately articulate I'd try to make myself more clear. I have a dipole with a coax feeding it and at right angle to it. I considered the 'one half of the dipole' that connects to the coax center conductor. I thought the other half of the dipole is then a V shaped conductor made up of the 'other half', and the feed line outer conductor. When the outer conductor is covered with high loss ferrites, I thought there would be excessive (maybe unnecessary) loss introduced in that V shaped half of the radiator.

I consider myself a successful since I've been able to get such good information from this group, even if I cant get this antenna to work.

If you're using a rig with pi-network output, use the 75-ohm line as if it were 50-ohm line. When you tune up you' ll not know the difference.

If you're using a rig with solid-state output without a tuner you may have a problem. But with a tuner, use it in place of 50-ohm line--you'll still not know the difference.

That's central to how the pitch circuit works. It's two oscillators mixed to product an audio product.

The volume on these units, works by sweeping the osc across a bandpass filter, converting FM to AM, and then taking that rectified energy and lighting the filament with it.
I won't use that approach, NS makes a fine VCA chip.

> As for your question about quadrupling the frequencies involved, I

We'd like them to be linear, aka one octave is the same size as another.

> capacitances of the frequency determining capacitors in the
> oscillators; then the hand capacitance becomes more significant and
> range changes become greater (the Theremin is more sensitive).

Right. Recent designs are about 30x more sensitive than the RCA design, and this may be why they are so "twitchy" to play.

> Throughout, I was presuming you have access to tubes as specified.
> For much of the circuitry, this is not too demanding (modern twin

I'm not going to duplicate it to that level, I'm just looking to produce
something that plays much like the original, without the large delay in
volume response caused by the filament driven approach that the RCA used.

I believe they are. The question is wether they were tuned to series
resonance, or off to one (which?) side.

How can i calculate the reactance of a short rod with relatively large
diameter?
The typical antenna is 20-30" and about 3/8" diameter.

The coil, I mostly understand, and I've got a fair bit of mathcad done now,
but I'm not seeing the light as to what the original designs were based on.

Some antennas match better to 75 ohms anyway, right?

I was kind of surprised when I discovered the fundamental difference between the two, and why 75 not 50, rules the cable world. For any given diameter of line (read cost per foot) 75 ohm cable is less lossy at high frequencies, than 50 ohm.. 50 carries more power than 75, because it keeps the voltages lower.

So it would seem that us VHF/UHF/Microwave guys should really be using 75 ohm cable!

Yes, that's correct.

There's a fundamental problem with determining feedline outer current with modeling. Whether conducted or due to coupling, the amount of current and its distribution depends on the length and orientation of the path along the outside of the feedline to the Earth. That means that the path not only to the rig, but from the rig to the Earth via its "ground" connection has to be modeled. While this might sometimes be simple, in many cases it's not. What you can productively do with modeling is to observe the effect in some general and theoretical cases, and see the effect of baluns at various points.

I believe you come from a test equipment environment, where "loss" can mean something other than power dissipation. For example, the "loss" of signal through a lossless RC filter, which is due to the combination of a fixed source impedance and filter impedance mismatch ("mismatch loss"). That IS the kind of "loss" we're trying to achieve with a balun. But dissipative loss, which is what I meant, isn't what we want.

In the following, "loss" will mean dissipative loss -- the actual loss of power in the form of heat.

A balun that's purely reactive (an air-wound coax coil is a good approximation) has very little loss in any case. But many effective baluns -- those using some types of ferrite cores -- are primarily resistive. The power loss in such a balun is simply I^2*R, where R is the balun resistance and I is the feedline outer current at the point of the balun. If the balun resistance is low, I^2*R will be small because R is small. If the balun resistance is high, I^2*R will be small because I is small. But there's an intermediate value of R for which I^2*R might be substantial. It's really an impedance matching problem -- the balun dissipation is greatest when the balun R "matches" the impedance driving the current. That's the approximate value you want to avoid. What I was alluding to is a balun that's distributed in such a way that the current at the position of a resistive core is significant, resulting in substantial I^2*R loss at the core. It's important to have enough R to reduce the current, hence the dissipative loss, to a low value.

I had the same problem with my 4btv. It turned out to be a cracked
plastic cap/seal that seals the top of the traps to the mast. I
ordered directly from the factory it was very reasonable. Before
assembling the trap I cleaned all the minor corrosion inside the trap.

Hi Dave,

I don't know where you got this theory of FM in the context of the
Theramin, it certainly isn't offered in the material as far as I can
tell. If it is, it is quite wrong. For one, there is no bandpass
filter anywhere. Second, the Volume Oscillator is used simply to pump
power into the heater of V5 efficiently. It is a DC-RF-Heater
conversion where the hand capacitance pulls the load to rob the
conversion process. V5 is simply a variable resistor plate load to V4
in a cascode design. V5 is a current limiter with R12 as a parallel,
very current limited plate voltage source tapped at 40% of B+. By
passing the hand nearby, the RF level is varied, causing the heater
voltage to follow and the tube conduction likewise. The circuit
frequency is selected only for conversion efficiency and at C13 is
driven to ground. As such the frequency completely disappears from
the theory of operation and has no part in the mixing products.
>
>> As for your question about quadrupling the frequencies involved, I

Which range? The quadrupled one? If it is already designed for it,
what is there to translate? If it is not currently the quadrupled
one, why are you translating it?

>
>I don't follow here. What's the load line?

The hand is robbing the power going to either circuit. Its proximity
is tailored to the plate load. The response of the circuit with
respect to the hand position creates what is called a "load line"
(consult tube amplifier design theory) that presumes the tube has a
given characteristic Z. Basically, this is ratiometrics and as the
hand, historically, has not changed Z then any change of the tube
characteristic Z (using the wrong tube in the same circuit) leads to a
different ratio whose effects may be pleasant, or intolerable.

Suggests that the ratio has gone ballistic - not a particularly
beneficial return. Would you try to tune a Cello like a Violin? Who
would want to play it?

>> Throughout, I was presuming you have access to tubes as specified.
>> For much of the circuitry, this is not too demanding (modern twin

Rectify the Volume Oscillator at the output of T3 and use it to
regulate a pass FET in cascode with the audio amplifier. Reference
the rectified signal to B+ not ground and observe polarity to perform
the same transconductance of the original circuit.

>> Returning to the question of coil construction. There is nothing

>
>I believe they are. The question is wether they were tuned to series
>resonance, or off to one (which?) side.

That is not critical. You should notice that the original didn't care
to offer tuning here, not in the conventional sense of alignment. The
controls are oscillator frequency tuning to maintain the "beat" not
resonance. I would speculate that the "Volume" control, C10 offers
some clue to the ratio of hand capacitance.

These antenna circuits may still be resonant, but to which side is
immaterial as the slope is the same.

>How can i calculate the reactance of a short rod with relatively large
>diameter?
>The typical antenna is 20-30" and about 3/8" diameter.

There are not large by any stretch of the imagination - not at a
wavelength of 300 or more meters. Their radiation resistance has to
be in the nanoOhms. Reactance is trivial, it is capacitive and based
on simple geometrical formula.

>The coil, I mostly understand, and I've got a fair bit of mathcad done now,
>but I'm not seeing the light as to what the original designs were based on.

That is because you are trying to see it in RF terms when it is no
more complex than a capacitive voltage divider that is used in light
dimmers. It only "looks" like radio, it is more an elaborate audio
buzzer. Going to higher frequencies is more likely to bring you
grief.

Greetings,

For 6-Meter work I have a Cushcraft 5-el beam.

I just came into possesion of an MFJ 3-el 6M beam. Not what I would chose if I was doing it on purpose, but since I have it I am wondering:

Is there any advantage (or disadvantage) to stacking these two antennas?

If not, maybe I'll mount the MFJ vertical for occasional FM work.

>For 6-Meter work I have a Cushcraft 5-el beam. I just came into possesion of an MFJ 3-el 6M beam.

>Is there any advantage (or disadvantage) to stacking these two antennas?

If you stack two identical beams, if memory serves me correctly, the maximum gain you could expect is 3 db over the single beam, and as I remember, stacking is to increase forward gain. Since you are stacking two different beams, the spacing, positioning, and feed would be critical in maximizing the gain. In my opinion, the difficulity in stacking two different beams versus the benefit gained would not make it worth the effort. It's possible that you could wind up with less forward gain than with a single beam, if you are not careful.

|Yes, that's correct.
|
|There's a fundamental problem with determining feedline outer current
|with modeling. Whether conducted or due to coupling, the amount of
|current and its distribution depends on the length and orientation of
|the path along the outside of the feedline to the Earth. That means that
|the path not only to the rig, but from the rig to the Earth via its
|"ground" connection has to be modeled. While this might sometimes be
|simple, in many cases it's not. What you can productively do with
|modeling is to observe the effect in some general and theoretical cases,
|and see the effect of baluns at various points.

Yes but... if we are concerned with induced current, then distance is
our friend.

|> the way to go. Thus my slightly tongue-in-cheek comment about loading
|> the whole length of coax with ferrite.
|
|I believe you come from a test equipment environment, where "loss" can
|mean something other than power dissipation. For example, the "loss" of
|signal through a lossless RC filter, which is due to the combination of
|a fixed source impedance and filter impedance mismatch ("mismatch
|loss"). That IS the kind of "loss" we're trying to achieve with a balun.
|But dissipative loss, which is what I meant, isn't what we want.

Let me give you a real world example, not from my test equipment environment but from a design environment.

The transmitter in the late version of the Phoenix Missile used as its final "amplifier" (really an injection-locked oscillator) a cavity with sixteen coupled Impatt diodes. This is difficult to describe in words, but I'll try

Each diode presented about -2 ohm, which was transformed up (or down, depending on semantics) to some "higher" value of negative resistance via some very low impedance quarter-wave coaxial lines. Each of these lines then became smaller diameter pins that exited one face of a radial cavity and passed through the cavity near the outside wall, thus coupling energy into and out of the cavity. On the opposite face of the cavity, the pins became an air dielectric coaxial line as they passed through another set of bores. Operating bias was supplied to the pins on the output side of these bores.

To "seal" the face of the second cavity wall we wanted to present a high impedance at the cavity end of each of the 16 bores. A low frequency equivalent would be the plate choke in an h-f amplifier and to prevent any energy from dribbling out to the power supply, we needed an equivalent of the B+ bypass capacitor.

The operating bias was supplied by 16 pulsed current sources at a classified frequency, but suffice it to say that we didn't want any bypass capacitors on the ends of these pins, not that they would have been effective at 10 GHz anyway.

The solution was to add some *dissipative* Eccosorb "dielectric" to these lines at an odd multiple of one quarter wavelength from the face of the cavity. The *magic* impedance inverting property of quarter wave lines was used to transform this low dissipative impedance to a

much higher, almost dissipationless impedance at the cavity.
I submit that the same thing can happen when using dissipative baluns.

Clearly, as you state above, we don't have much of a clue as to the surge impedance of the outside of the coax or its effective length so computation can be difficult. But intermediate values of balun resistance aren't necessarily bad if they are located at a position that minimizes I.

For broadband applications there is probably some optimum way of populating the line with ferrite, but this is likely an intractable problem, best solved by making the whole length of the line ferrite, which is where I came in. [g]

Wes

|
|In the following, "loss" will mean dissipative loss -- the actual loss
|of power in the form of heat.
|
|A balun that's purely reactive (an air-wound coax coil is a good
|approximation) has very little loss in any case. But many effective
|baluns -- those using some types of ferrite cores -- are primarily
|resistive. The power loss in such a balun is simply I^2*R, where R is
|the balun resistance and I is the feedline outer current at the point of
|the balun. If the balun resistance is low, I^2*R will be small because R
|is small. If the balun resistance is high, I^2*R will be small because I
|is small. But there's an intermediate value of R for which I^2*R might
|be substantial. It's really an impedance matching problem -- the balun
|dissipation is greatest when the balun R "matches" the impedance driving
|the current. That's the approximate value you want to avoid. What I was
|alluding to is a balun that's distributed in such a way that the current
|at the position of a resistive core is significant, resulting in
|substantial I^2*R loss at the core. It's important to have enough R to
|reduce the current, hence the dissipative loss, to a low value.

In later versions, it's done that way. The volume osc is FMed by the hand
(or swept, pick your definition) and the output run through a filter. So, as
you sweep the osc, it's amplitude varies.
Another approach is to use a second ref osc, and mixer, and use that beat
product..

Right, we only care about the amplitude.

> what is there to translate? If it is not currently the quadrupled
> one, why are you translating it?

The one I have is set up to operate at 750-800 kHz.
However, they didn't design in these antenna loading coils.
It is also extremely twitchy to play.
Another fellow measured the sensitivity of this one, and a couple others,
and the RCA design.
The RCA was roughly 30x less pitch change per pF.

> different ratio whose effects may be pleasant, or intolerable.

Ok, I think I understand. The oscillator is "weak", and the hand proximity moves it twoard extinction. This makes sense, the Lev Theremin and the RCA designs are maximum volume with the hand removed, and go to minimum in proximity. It also makes musical sense, as I need to be able to get the note terminated quickly to play real music, as opposed to wierd sound effects.

> >We'd like them to be linear, aka one octave is the same size as another.
>
> Then you need to know the ratiometrics.

That may be what I'm trying to uncover, but the pitch and volume controls are very different.
The pitch is far more important to be accurate.

> Suggests that the ratio has gone ballistic - not a particularly
> beneficial return. Would you try to tune a Cello like a Violin? Who
> would want to play it?

Good question.
If you listen to recordings of Clara Rockmore, the sound is much more controlled, and precise.
I suspect that something has been lost in the design of the antenna coils, and how they interact with the player. Also, I think that the sensitivity overall has suffered from a "more is better" approach, which shrinks what Clara called the "space control field", that area around the instrument that must not be infringed on while playing. This by itself isn't a bad thing, but it appears to come at a large cost in playability.. Like adapting a Cello for a marching band. :)

> Rectify the Volume Oscillator at the output of T3 and use it to
> regulate a pass FET in cascode with the audio amplifier. Reference
> the rectified signal to B+ not ground and observe polarity to perform
> the same transconductance of the original circuit.

RCA did it with filament heat, which introduces a significant delay, and overall slow response.
Moog does it with the bandpass and rectification, and an LM13600 VCA.
PAIA does it with another pair of oscillators, and does a crude F-V conversion on that mix product. I'm not sure which is really the better approach.
Interestingly, the PAIA approach may be closer to the Lev Theremin and RCA designs.

Don't mix the two circuits. The pitch is much harder to control, and much more critical.
See further down also

> These antenna circuits may still be resonant, but to which side is
> immaterial as the slope is the same.

I suspect it is important. There is some information that isn't in the manual.
Bob Moog worked on Clara Rockmore's theremin (an original Lev Theremin box), and there was some adjustment made to the operating frequency, to get it playing "right". I think the coil is designed to some frequency point, and the control oscillator made to run at, below, or above that point, to get the tuning slope to work out as best it can, then the reference oscillator is tuned to set the base pitch. It seems reasonable that the behaviour would be different if the control osc is set for those three points, against the same hand motion.

I get that, it's about the size of my 2 meter vertical, other than the rather large diameter.
I meant large, in that Theremin could have easily used something thinner, yet he didn't.
There was likely a reason. Wether it was mechanical rigidity (likely) or cost of materials, or that was the easiest size to get, I don't know. But, I expect the diameter of the rod to have a significant effect on it's capacitance, and how well it couples to the player.
I also see that there is never a picture of a Lev Theremin designed box, with a pitch antenna of any other shape, like a flat plate.. Important, I don't know..

> buzzer. Going to higher frequencies is more likely to bring you
> grief.

The volume and pitch are more or less separate entities. I'm not much concerned with linearity of the volume control. You're far more likely to notice 5% errors in pitch, than in expression.
On the pitch side, you just have two oscillators, mixed in a diode ring (modern design)

What I think may be going on here, is that the ideal antenna coil design moves you to a region where each inch of motion of the hand is more or less linear in pitch.

IOW, if the first foot is an octave, then ideally the second foot would also be an octave.
This would obviously break down when you get very close to the antenna, as touching it would be a huge jump, but that's the goal..

The difficulties are part of the exploration. Trying to apply it at a different frequency is likely to uncover the bits that are important and working, because they scale, and to introduce other issues, which may just get in the way.

Unfortunately, Theremin didn't leave behind much in the way of notes, so we don't know WHY he did certain things, only what was done.

The terk is a vertical loop, with two nulls, and a fairly broad response.
They did not speak accurately.
It would have to be something like a vertical colinear antenna, to be
vertically polarized, omnidirectional, and have gain.. I'm not sure how
important polarization is at 1 MHz, over moderate distances. I don't work
down that way much.

However, there could be an advantage-- by COMBINEING them! But this
takes some real estate to accomplish or towers! for example have
friend , has old modified Wilson for 6 meters , in a tree at around
90-110 feet, fed with hardline. he also has a 10 El m squared at around
40 foot, on a tower. During band openings, he hears better with the
tree mounted ant, other times , better with the M squared. Tho, dont
think he ever combined them (Tee fitting, and adjusted phaseing), it is
possible to max for shifting signals! in microwave (corse, there they
use 2 recievers)! it is called Space Diversity! at , say 2 GHz, path of
a far end station may move up to couple hundred feet-- for Es, and
tropo, the same effect may occur, shifting max to min (or vice versa) by
300 feet, or more! Would be really interesting to see a paper on this
at VHF (read 6, 2, and 432)! Jim NN7K

Hi Dave,

Couldn't be important, the slope is the same to either side. And if
it was at the peak you would lose half your range of motion.

You might want to think of the Q of the situation. For your recent
re-inventions with 30x the characteristic, it would seem an engineer
stepped up to the Stradivarius and "optimized it" (better Q?).

This seems to be theory paving its own road in front of itself. It
sounds good, looks like performance correlated to hand waving (in the
musical sense), but is unrelated to what is going on.
>

The design is first and foremost for the benefit of the performer, not
for the technical resonance.

>But, I expect the diameter of the rod to have a significant effect on it's
>capacitance, and how well it couples to the player.

More than likely, it goes to the surface area of half a plate
capacitor.

>I also see that there is never a picture of a Lev Theremin designed box,
>with a pitch antenna of any other shape, like a flat plate.. Important, I
>don't know..

Your speculations below may be prescient.

>> Reactance is trivial, it is capacitive and based on simple geometrical
>formula.
>
>Which is the part I'm looking for.

Simple, compute the surface area of the smallest plate,
divide by the distance between plates;
multiply by 0.225 (for dimensions in inches).
you get picofarads. Let's speculate:

One hand = 24 square inches
One rod = 24 square inches (how convenient)
distance between them = 12 inches
or about ï¿½ pf -whew!-

Actually it would be less than that because the plate of the rod is
elongated. If we bring the hand closer to the rod, say, within an
inch; then the capacitance rises about 10 fold. But again, probably
less because of the distribution of the rod's area.

Anyway, working numbers of .5 to 5 pF. You may note that almost every
capacitor in the box is easily 20 to 2000 times this and swamps it
out. So it may be reasonable to presume that the slope of a curve is
being used to leverage the small reactive change.

>What I think may be going on here, is that the ideal antenna coil design
>moves you to a region where each inch of motion of the hand is more or less
>linear in pitch.

Well, given the shape of the rod, that is arguably false. But we can
proceed with the suspect numbers above as if it were true.

>IOW, if the first foot is an octave, then ideally the second foot would also
>be an octave.
>This would obviously break down when you get very close to the antenna, as
>touching it would be a huge jump, but that's the goal..

There is no reason for this to fail, unless we revert to the reality
of the capacitive distribution of the rod vs. the hand. Anyway the
speculation of octaves does not "ring" true to my recollection of

hearing the Theremin, which to me encompassed more than a single
octave.

>The difficulties are part of the exploration. Trying to apply it at a
>different frequency is likely to uncover the bits that are important and
>working, because they scale, and to introduce other issues, which may just
>get in the way.

Try by deliberately spoiling Q for the "hot" modern versions that are
hard to tame. This may be the Q of the coils (unlikely) or the
feedback systems of the oscillator controls which have been
"engineered" instead of crafted.

>Unfortunately, Theremin didn't leave behind much in the way of notes, so we
>don't know WHY he did certain things, only what was done.

There is no reason to believe he understood it either. After all the
guy that invented the Moog decided being a he wasn't what she wanted.

That part I see, about the peak.
But if the coil SRF is below or above the oscillator's operating point, then it seems to me that the degree of pull for a given change in hand capacitance should be different.

> You might want to think of the Q of the situation. For your recent

That may be, Theremin didn't have much in the way of test equipment, and radio was in it's infancy.

Sounds plausible,

> Actually it would be less than that because the plate of the rod is
> elongated. If we bring the hand closer to the rod, say, within an
> inch; then the capacitance rises about 10 fold. But again, probably
> less because of the distribution of the rod's area.

So the shape of the rod makes the changes more linear. Makes sense.
The diameter of the rod, then should be as small as possible to achieve the mechanical rigidity needed. All bets for accurate pitch control are off, if the antenna is waving in the breeze.

Possbly a blade or triangular, or even an airfoil shape might be interesting, with the "trailing edge" pointed at the performer. That would

tend to maximize this effect.

> Anyway, working numbers of .5 to 5 pF. You may note that almost every

> being used to leverage the small reactive change.

That's where I'm thinking that the Q and SRF point of the antenna coil comes
into play.
Also in linearizing it, to the degree possible.

> >What I think may be going on here, is that the ideal antenna coil design
> >moves you to a region where each inch of motion of the hand is more or
less

I see that the area nearest the hand is obviously more effective than the
area away from the hand.
A bit nasty to model though..

> There is no reason for this to fail, unless we revert to the reality
> of the capacitive distribution of the rod vs. the hand. Anyway the
> speculation of octaves does not "ring" true to my recollection of
> hearing the Theremin, which to me encompassed more than a single
> octave.

Four or five octaves isn't uncommon. The trick is to get it as close to one
octave per (convenient unit of distance) over as wide a range as possible.
If it is nice near the middle and a bit non-linear at the ends, then that
wouldn't be too bad.

> Try by deliberately spoiling Q for the "hot" modern versions that are
> hard to tame. This may be the Q of the coils (unlikely) or the
> feedback systems of the oscillator controls which have been
> "engineered" instead of crafted.

The modern designs all use very small coils, on the order of 40mH, with very
low SRFs.
I suspect they aren't really doing it right. Hard to believe that four
small 10mH coils act like a physically much larger coil. This is why I
suspect Q of the antenna coils is involved somehow.

> >Unfortunately, Theremin didn't leave behind much in the way of notes, so
we

A most interesting and informative page, and agreed on the control. I never heard of the filament method of gain control before, very nice. Was this based on prior art, or was it a new idea then?

Which leads to a question, on a Moody Blues album from about 1970, a theramin was used to start a song, which swept from around 30 or 40 hz, by ear counter, to at maybe 17000, which was the top end of what I could hear then and possibly above what a british LP ever could hit then. (See slew rate limiting) Anyone know what type of theramin that was? The sweep was very very smooth, and took almost 30 seconds as I remember, so must have been somewhat easy to control.

Stacking 2 non-matching antennas is probably not going to work. I won't say never, but it will be close to that.

The Cushcraft 5 elements were very poor performers for the length. The antenna is an excellent parts kit, however. You can make a very nice 4 element out of it that has a good pattern and good gain. Or a 5 element if you stetch the boom.

On Wed, 28 Jul 2004 17:02:15 GMT, "Jerry Martes"
<j.jmartes@verizon.net> wrote:

[snip]
|
| Let me begin by identifying myself. I'm an old guy who doesnt know much
|about current electronic technology. I'm just having fun with this project
|of making a home made antenna that isnt expected to perform as well as
|designs that are already available.

Don't be too sure! You are not automatically doomed to failure.
|
| I thought the loss in the dissipative ferrite tubes slipped over the
|coax's outer conductor might absorb some "power", and thereby introduce an
|overall insertion loss.

They indeed may absorb *some* power. Whether this is important or
not is the question.
|
| If I was adequately articulate I'd try to make myself more clear. I have
|a dipole with a coax feeding it and at right angle to it. I considered the
|'one half of the dipole' that connects to the coax center conductor. I
|thought the other half of the dipole is then a V shaped conductor made up of
|the 'other half', and the feed line outer conductor. When the outer
|conductor is covered with high loss ferrites, I thought there would be
|excessive (maybe unnecessary) loss introduced in that V shaped half of the
|radiator.

Look at it this way.

Case 1) For a moment consider that the feedline is not connected to
the antenna (a center-fed dipole). If it is located exactly at the
feedpoint and is 90 degrees to the dipole, then it is equally coupled
to each half of the antenna and there is no induced current in the
wire. You can do anything you want to this right-angle "wire" and
there is no power lost to the system and no effect on the radiation
pattern or feedpoint impedance.

Case 2) The coax is located as before but now connected to the dipole.
I haven't seen Roy mention it in this thread but he wrote an excellent
paper on this: "Baluns: What They Do And How They Do It", The ARRL
Antenna Compendium, Vol 1, pp.157-164. Another valued contributor to
this knowledge base is Walt Maxwell, W2DU of "W2DU Balun" fame; also a
frequent contributor here.

To summarize, when you connect the outer conductor of the coax to the dipole, that half of the dipole is comprised of two parts, the original wire and the new wire (the coax braid). The available current on that side will divide into two currents, with the relative magnitudes inversely proportional to the impedance of each wire.

If you want to keep the current in the coax braid low, you need to make its impedance high. That is the function and purpose of the balun. This impedance can be purely reactive, purely resistive, or more typically, a combination of the two (complex).
Quarter-wavelength sleeves, a coiled length of coax and stub baluns are almost totally reactive, ferrite bead/sleeve baluns depending on the ferrite can be either nearly resistive or complex. Clearly, those that are purely reactive are non-dissipative and those that are partly or totally resistive will dissipate power. To solve this problem, the high impedance (i.e. balun) should be located at the feedpoint.

Case 3) The coax does not exit the dipole at 90 degrees. There will be unbalanced coupling to the two halves of the dipole, thus there will be current induced on the outside of the cable. In this case the radiation pattern of the dipole (or other antenna) is corrupted to some extent. Whether this is a problem is---well---problematic... it depends.

If you are carefully constructing a highly directive antenna (your case) then this messes up your pattern. If it is your 80 meter dipole, then who cares.

In this case you should know that even if the transmission line is balanced, the same effects occur. Also in this case, the optimum position for the balun *might not* be located at the feedpoint. Unfortunately, this is really problematic because the optimum location isn't easily determined. The best bet is to avoid this case when clean patterns are desired.

As an aside, I am often amused when someone will mount a Yagi polarized vertically, even going to far as to place it on a non-conductive mast and then tape the coax to that same mast.
|
| I consider myself a successful since I've been able to get such good
|information from this group, even if I cant get this antenna to work.

Hang in there.

Wes

[Recall Junior has tons of 75 ohm CATV cable, and wants to make a 50 ohm cable.] Recalling the way resistors and capacitors can be hooked in series or parallel, say, do parallel cables halve or double the ohms? One center lead to one side of the dipole, the other center lead to the other side of the dipole. The braids hooked together I suppose. Or, both center leads hooked to top side of dipole, both braids hooked to bottom side of dipole. All kind of combos possible. Wait, this is all a waste of cable. OK, never mind.

896. little radios with big antennas

Perhaps little radios and big antennas don't mix for transmission no matter what.

Will Junior fry his Kenwood TH-F7E handi talkie by hooking it to larger 2m Ham antennas?

He can't wait for Christmas. Confident after reading the "make 50 ohm cable from 75 ohm cable?" thread, his eyes turn toward the 75 ohm _family VHF TV antenna_. Will trying to transmit 144 MHz at 5W thru it fry his handi talkie?

Cross-posted to: alt.energy.high-voltage,rec.radio.amateur.antenna,rec.boats.cruising

I am Ram , Ph.D. Student

Dear sir/madam,

I am trying to find out the correlation between the time delays in conduction mechanism and the degree of earth resistance.

I am using PSPICE simulation package for the simulation work , any suggestions to give help welcome

Research Title:

INVESTIGATION OF THE TRANSIENT BEHAVIOUR OF EARTHING SYSTEMS SUBJECTED TO HIGH IMPULSE CURRENTS

One of the research objectives is to observe the correlation between the time delays in conduction mechanism and the degree of earth resistance for different soil resistivity, impulse polarity and earth electrode configuration

Time delays can be defined as the time taken to reach the current peak. Generally, the time delay can also be influenced by non-uniform water settling process, drying and heating in soil and of course due to the statistical nature of air breakdown. However, these influences are neglected in determining the correlation between the time delays and earth resistance reduction.
In the previous studies, the time delays in soil due to ionisation and heating have been plotted against current/voltage magnitudes. It was found that the time delays were decreasing with higher currents/voltages. However, the tune delays were also taught to be due to a statistical nature of air breakdown.

If you have any question welcome

I am looking forward to hear from you soon

Thanks in advance

Ram

That looks like good advice, because angles of arrival vary a lot between short-skip Es and long-skip DX. It's really handy to have a separate antenna whose peaks and nulls in the vertical pattern will be at different angles from your main antenna.

>and beg/borrow/steal/make a switch to check signals between the two.

Signals on 6 can change very quickly - especially the *real* DX - so it's very important to be able to swap instantly. That means two separate feedlines and having the switch where you can reach it.

Better still would be a switch that gives you all the options: Upper only / Lower only / both In-phase / both Antiphase. There are details in the ARRL Antenna Handbook, and on the web. That option requires two separate feedlines of carefully measured electrical lengths, but it is also the most powerful option.

As others have said, normal in-phase stacking of two different beams is not promising... but you never know, there might be a vital QSO where that combination is best. Likewise, antiphase stacking (switching in an extra electrical half-wave into one feedline) would dramatically shift the peaks and nulls in the vertical pattern, which might be very useful someday.

The "U/L/I/A" setup may seem like a lot of effort compared with a simple changeover switch, but it's what many of the most successful 6m DXers and contesters use.

[speculative input]

It seems that channels of higher conductivity in a low conductivity
matrix would lead to longer times to peak I in that there would be
fewer parallel current paths, and consequently, higher effective
inductance in the path.

John

Note that I didn't say never. I also didn't say the Cushcraft 5 didn't work, just that it wasn't as good as it could have been. And they really are a great parts kit, we have 2 hanging in my buddy's pole barn that gave good service in the early 90's as portable contest antennas. One rebuilt as a 4 element, and one as a stretched 5.

Remember, he didn't say just put the 2 up and switch between them, he said stack them. It will likely be a lot worse than either of the 2 antennas singly. At least model it first, and see what is needed to, at a minimum, get them close to being in phase with each other.

Or do what you said, though the 5 will likely do better, and just put that up as high as possible would be my vote.

Bob - if you'd like a decent rework of the thing as a 4 element, feel free to drop a note to the email address shown here and I'll dig it out of my files.

And yes, sometimes 6 can be amazing. During the late 80's peak I was working an AK station, I think it was KL7NO, and he was about 60 over.

So he went into his basement, fired up his FT690 on the telescoping whip, and work myself in EN34, and another guy in EN35, at well over S9. And was still in his basement when he did it.

Agreed - at our contest site we use a 4 over 4 stack with a separate 3 element under that. Not as fancy as you suggest, or I'd like, but it really does help in a contest. That and they don't have to point the same direction at the same time. Helps when 2/3/4 is in at the same time as 7's.

Time-related transients in systems of conductors are more accurately analysed by considering the conductors to be transmission lines. Propagation velocity and characteristic impedance are essential features to be approximated. Reflections are also important factors.

Applies equally to lightning conductors.

Now carry on with your thesis.

Reg Edwards.

I agree one is right to be "concerned" about carbon and flue gasses however, I would not let that stop me. I have run an antenna over a fireplace flue for years without a problem. Just be sure the antenna is as high as you can get it and hopefully that will be at least 3 or 4 feet above the flue top. Then air and wind will have a chance to disperse the gasses before they get to the antenna in any concentration.

I hate to see people do nothing just because they think there might be some possibility it is not the best way to do it. Put the antenna up and if you have to take it down and clean it in a few years, no big deal.

I hear you Craig! I've got a copper-pipe J-pole tuned to 156.800 marine on
my chimney, as you eventually run out of roof space for antennas <G>

It's putting the log periodics or other beams on a chimney, where elements
will likely spend some time right over the flue that would see the real
effects, but as you said, any location is better than in a box on the garage
floor, lol.

Reg, I think he might be referring to the transfer-times from a conductor to different components of soil. Not the transmission line theory inside a conductor. The reaction speed of ground systems are under a lot of study to help determine the best control of ground potential rise (GPR) where isolation by fiber optic or HV isolation transformers alone is insufficient protection.

Water/wet soil along the soil surface during a strike attachment makes it hard to control GPR when it connects multiple earthing points almost instantaneously. The dry-ground sections of each earthing rod end up making less contribution to the designed voltage division, and increased current from grounding systems up into the interior of buildings is one result. It's an interesting problem creates and conflicts between design approaches for lightning protection. What works for direct attachment will not work for the near-field, in other words.

Best regards

Jack Painter

I don't see any of that BS because I've put in some nice filters. Messages from the known trouble makes (ie: Dan and Bruce) are automatically deleted, so I don't see them. Messages containing topics known to be trouble are also deleted.

All that is left is good posts with helpful responses.

Thank you for taking the time to read this.

Your Freedoms are in jeopardy! RadioShack Corporation has filed an injunction in a Texas Court that has shut down an opinion website, http://www.radioshacksucks.com, in direct violation of the Freedoms of Speech, Expression and Peaceful Assembly, as guaranteed to us by the Constitution of the United States. If other companies learn of this, they will use it against any website that speaks out against that company. This is extremely dangerous, as it will change the face and scope of the Internet.

If Big Business continues to dominate our lifestyles, we will lose our freedom to worship as we see fit. We will lose our freedom to vote for the candidate that we think will do the better job. We will lose our freedom of the press to accurately report on current events. We will lose everything we have fought and died for in the past 228 years Do not tell this to the descendants of those that have bravely fought in previous battles and wars, for their ancestors would have died in vain. The Constitution will have been overruled by Big Business.

RadioShack is on a vicious witch hunt and will not stop until they dominate our lives. RadioShack must be stopped now, before it gets any later or any worse.

Here is what you can do to help: copy this letter and add your signature to the bottom. Mail it to the following people:

Leonard H Roberts
CEO RadioShack Corporation
100 Throckmorton Plaza
Ft Worth, TX 76102

The Honorable Kenneth Curry
401 W BELKNAP
153RD DISTRICT COURT
FORT WORTH, TX, 76196-0225

Thank you for your help and support.

>RadioShack is on a vicious witch hunt and will not stop until they dominate
>our lives.

Hmmm.. I thought they were just trying to help out when people need
electronics.

Actually, I've found RS to be friendlier, better stocked, and less prone to
insist on trying to sell me a cell phone recently.

They switched their parts SKU's to drawers a while back, but they still have a
pretty good inventory. The local one here is fun to visit, and a ham is the GM.

I like going there. Can't always say that was so, but a good place these days.

Hope this helps. My speculation is that if an injunction was issued against
that web site, it was for interference of business and/or libel. Appears the
judge must have thought the case was compelling.

Just bought the MFJ-269 antenna analyzer.

Got the MFJ accessory pack, 99C, with 10 rechargeable batteries and the MFJ 1312D AC adaptor, which has 12 volts dc output.

Instructions for trickle-charging batteries inside MFJ antenna analyzer say an external source of "at least" 13 volts is needed -- and sez the MFJ 1315 supply will do this.

Looked at the MFJ web site -- they seem to no longer sell the MFJ 1315 supply.

How the hell do I charge up my batteries, using the analyzer's built-in trickle charger? The 1312D adaptor seems to be about a volt short, at 12 volts output. Anyone tried using that adaptor?

I've seen a selection of "wall warts" at just about every flea market I've been to, and have added quite a few to my collection from various defunct and obsolete pieces of equipment. A lot of them put out 15 volts or so DC at a couple of hundred mA, which is what you need. If you don't want to wait for the next flea market, try Radio Shack or a radio or computer parts store like Fry's, or eBay. You might have to replace the connector with a compatible one, and be sure the polarity is correct.

Roy Lewallen, W7EL

> fry his handi talkie?

I can't imagine why it would.
The TV antenna is a log periodic, though it isn't really designed to cover this band.
The Balun at the top may be marginal at 5W, maybe not.
TV antennas are horizontally polarized, and most VHF FM work is vertical, so this is pretty much a bad idea, but not fatal.

However, an HT's output has to take into account a highly variable antenna impedance, so while I wouldn't expect very good results, I also wouldn't expect any smoke.

I'd suggest Jr build a tiger-tail first, or as my nephew did once, sit on a National Guard tank.

Hooked in series, double; hooked in parallel, half.

>Wait, this is all a waste of cable. OK, never mind.

Hi Dan,

No. You already asked. Yes, a waste of time because you don't get
any benefit of "higher Z" through twin lining it - the overall loss is
still the same. Now, if you simply ignored the inner, stripped off
the coax jacket (reported as lossy), built spacers and used the
shielding as paired conductors; then you may observe some benefit.
(Who said free was cheap?)

Well, for starters you might bring Ted Hart out of the woodwork to tell us how he changes the phase between the electric field and magnetic fields in his 'EH' antenna to increase the gain. It seems to me there might be a few good whoppers there.

Why, he reverses the direction of the Poynting Vector. I thought everyone knew that. Goes into the "antenna" instead of out.

just use the 75 ohm stuff in place of the 50. nothing special needed, swr only slightly affected. don't pick nits, get on the air.

btw, parallel cables by hooking their shields and center conductors together gives you 1/2 the impedance of one alone, so two 75 ohm ones in parallel give 37.5 ohms. this can be useful when building matching networks for stacks of yagis or other situations where you need an impedance transformer.

try searching your library for recent papers by leu and darveniza (i hope those spellings are correct) and john anderson. check cigre, ieee, and recent iclp papers. if your university can contact epri you may also be able to get some reports on our research from there.

Hal, if it is digital in the AM band and digital in the FM band then how can we differentiate if we dont call it AM digital and FM digital? I think you should visit the designers site at www.ibiquity.com for some enlightenment.

What's wrong with Radio Shack, anyway? I bought something there both yesterday and today. Had what I wanted a cheap enough. No problems.

Anybody can sue anybody. Why should this upset anybody. That's the American way. Sue enough people and you might even become a politician......maybe even a presidential or vice-presidential candidate. My freedoms are certainly not in jeopardy because RS sues somebody....quite the opposite. This just shows what freedoms we have.

Exactly, I guess that is why they have a whole section devoted to transmission line theory, and a section devoted to circuit theory. They differ.

When 6 meters is open it does not take much of an antenna. The first contact I made on 6 with a transverter I just finished was from North Carolina to Canada using about 10 watts to a trapped dipole cut for 40 to 10 meters. It was the only antenna I had up for anything lower than 2 meters and I just wanted to see if I could hear anything on the transverter. I bought a 5 element CC because I just read the end of the box and it said 50 to 54 mhz. I did not take time to see that it could only be tuned for about a mhz or two before the swr went way too high. I later extended the boom from about 12 feet to 16 feet and it made a noticiable differance on the signals when there was no skip.

As usual CC puts too many elements on too short of a boom.

939. FS**MFJ ITEMS (tuners,etc) and GRID DIP METERS**

Hello gang. Here are some MFJ items,and some grid dip meters. All items are PLUS shipping and boxing from 96002.

Eico 710 grid dip meter w/coils and manual. In the original box and looks almost new. $20.00

Heathkit grid dip meter w/coils and manual. fair to good cond. $15.00

MFJ Differential-T 3KW tunes. In ex.cond. Only low power used with it. $150.00

MFJ Versa Tuner III model MFJ-962C 1.5KW tuner in ex.cond. Only used with low power. $125.00

MFJ-941D Versa Tuner II 300 watt tuner in very good cond. Only used with low power. $40.00

MFJ-202 Noise Bridge in very good cond. $15.00

MFJ-525B RF Speech Processor in good cond. Some scratches on case. Face is fine. Great reveiws on this unit. Nice for old BA equipment that does not have built in pros. $40.00

MFJ-207 HF SWR Analyzer in ex.cond. Original box and manual. $20.00

MFJ-752C Signal Enhancer II. Audio filter. In good cond. Scratches on face. $20.00.

Pleas email me direct at kf6ikc@sbcglobal.net if you responed to the list I probably wont get back to you as I do not read them often.

Take care,Stan

You might not see the offensive side of Rapier, but if you look up his harrasing messages spanning years on sci.environment you'll see what I mean.

James Rapier from old Kentucky way believes the lies that Killers feed the public. Killers Koch would just as easily have killed James Rapier as Killer Koch's did Danielle Smalley and Jason Stone, except just by accident it was Smalley & Stone instead of Rapier that lived near Koch's pipeline. For 11 years Koch's never spent a dime inspecting that pipeline. This is the America that Rapier wants for everybody, where Killers spend $60,000,000 of Organized Crime money subverting America through a series of crooked think tanks and paid-off science-hoax "Whitecoats" liars. Not one scientist arguing against global warming is found free from Koch puppet-strings through Koch'ss organized crime empire of think tanks -- NOT ONE! There is not one single scientist in North America disputing Global Warming except those on the corrupt payrolls of dirty killers like Koch.

James Enviro-Rapist is a sucker for Koch propaganda. Rapier has a big fat Koch in his mouth that he is sucking on. "Blowjob Rapier's" morals suck, and he is not qualified to participate in public affairs.

Here are the Global Warming counterfacts (partial list):

* 1992 -- "Warning to Humanity" petition circulates, signed by 1,700 working CREDIBLE scientists.
* 1992 -- Oil, Coal, pollution-industries counter-attack at Rio conference, fake Heidelberg Appeal circulates with their funding, using their paid-science-traitors, like the documented corrupt Fred Singer, documented corrupt Fred Seitz, documented corrupt Bruce N. Ames.
* 1997-1998 -- hottest ocean temperatures ever recorded in human history.
* 1998 -- hottest year in recorded human history.
* 1998 -- 86% of all corals bleached, came 2 degrees from known heat-death of species, and 10 days away from known heat-associated digestion failure starvation deaths. No fossil record shows such massive simultaneous incident ever in global geologic history other

than 5 mass extinction incidents.
* 1999 -- strongest super-cyclone (310km/h winds) in human recorded history hits Orissa, India. 1.9 million houses damaged or destroyed, 10,000 people swept out to drown at sea.
* 2002 -- Severe droughts on five continents simultaneously -- at one moment the crops to feed one sixth the human race are threatened by brutal killing weather.
* 2002-2003 -- Worst drought in Australia recorded human history leads to wildfires invading Austrialian capital city and burning down hundreds of city blocks. At one moment not long afterwards a 250 kilometer firefront threatened to engulf the entire largest city in that country, Sydney.
* 2003 -- More people displaced by flooding than any year in recorded human history, over twice the geographical area flooded than second-worst flood disaster year in recorded human history.
* 2003 -- 562 tornadoes sweep the USA in ten days -- largest swarm of tornadoes ever recorded in US history, almost 50% worse than previous historical record, and nearly three times worse than any May in US history.
* 2003 -- Largest hailstone in human recorded history falls in Nebraska, 18 inches diameter, "cannonball size" which denialists say is impossible according to THEIR understanding of physics. Canteloupe-sized, softball-sized, baseball-sized, golf ball-sized all fell in 2003 hell storms.
* 2003 -- Weeks of unrelenting pounding of constant storms finally break northeast US power grid, 50,000,000 utility customers blacked out in US and Canada. Indiana governor, Frank O'Bannon, dies of heart attack from stress of one declared sequential "state of emergency" after another. Indiana, Ohio, Pennsylvania, Illinois, Toronto especially hit hard.
* 2003 -- Worst forest firestorms in Portugal's recorded human history, blamed on excessive heat and changed air currents denying rainfall.
* 2003 -- 20,000 forest fires in Russia, 16,000 of them before the heat of summer, the largest number in human recorded history.
* 2003 -- 1,400 heat-stroke deaths in Andhra Pradesh, India from sustained heat wave and delayed monsoon -- largest mass heat-killing in local recorded human history.
* 2003 -- 35,000 excess heat-stroke deaths across Europe, largest mass heat-killing in European recorded history.

Must agree- Until about 15-18 years ago, cushcraft made (and so did
Hygain, ect) some real doozies for all bands, and had some of the most
outrageous claims for gain, when selling (advertizeing) them. This is
WHY the ARRL , until recent times wouldn't allow gain claims, unless you
could back them up!!
These are in the old "VHF'er magazine, gain MEASUERMENT CONTESTS!

Nov- 1965, San Jose Antenna contest:
64 El. Broadside Cushcraft (colinear) Measured gain-- 8.5 DBd !
16 foot Telrex 420M2116 Gain 9.2 DBd
and a real winner! 13 el HY-GAIN yagi Measured GAIN +1.0 DBd off the
front, but WAIT: measured GAIN of 9.0 OFF THE BACK !!!
And another TELREX 15 el yagi (probably no balun): - (yes thats NEG.
12 DBd off the front, but had a gain of + 6 DBd , off the side!! These
are all 432 ants, but you get the drift! And, BTW, the WINNER of thisw
contest was a 32 El. Extended Expanded Colinear (Frank Jones Handbook
with 18.6 DBd gain)!! If you have older ads for these , compair the
gains! But, after over 40 years on six, can personally verify that
power required is next to NOTHING, on a good opening (even had the power
to NILL, and carried on qso- even worked guy in Pennsylvania from
Oregon, with aprox. 50 PICOWATTS)! Granted, during F2, but -- oh well,
yours for consideration Jim NN7K

I live in a fairly un populated area in Bradenton Florida. There is a lot of trees around. I have a weak signal if I can get one at all how can attach somthing to my balcony of my house preferably a multidirectional antenna, so I don't have to aim it just right. Somthing similar to a marine Vhf or Loran antenna or something on that line. My two reasons for this are I dont want to deal with the home owners association or lightning. My other problem is my family has three carriers one alltel one tmobile and cingular. will one antenna work?

Also I was in Idaho in a valley and I coudnt get a signal at all what can be done there. Thanks Mike

I'm not sure you can extrapolate this to the problem at hand. For an illustration, open the EZNEC model VHFGP.ez, and add a wire from 0,0,5 to 0,0,3.25, 40 segments. This will behave like a more-or-less worst case transmission line. You'll see that there's substantial current on the new wire, with a maximum at the top -- where it connects to the ground plane -- and cyclic loops of current along its length. At about 1/4 wavelength from the top, the current is very low. Insert a load at that point (14% from end 1). You'll see that a low impedance at that point isn't transformed to a high impedance at the top of the wire. In fact, it doesn't matter hardly at all what impedance you insert at that point -- it has very little effect on the current at the top. This shouldn't be a surprise, since elementary circuit theory tells us we can insert any resistance at a point of zero current without upsetting anything. A resistance at the top of the wire, though, will reduce the current at that point.

Now set the power to a constant value, say 100 watts, via the Options menu, and look at the power dissipated by a load inserted at the top of the wire (wire 6, 0% from end 1). Maximum dissipation (about 2 watts) occurs with a load resistance of about 100 ohms. The current at that point is minimized with a high resistance, although it doesn't have much effect on the current on the rest of the wire beyond about 1/4 wavelength from the top. In this interesting case, you need a balun at an odd number of quarter wavelengths from the bottom of the wire to suppress the induced current, and another at the top of the wire to suppress the conducted current.

Put a single load about a half wavelength from the top (29% from end 1), at one of the current maxima. You'll find that you can get up to nearly 6 watts dissipation in the load (seen by clicking Load Dat) by varying the load resistance, with the maximum at about 100 ohms. If you add a second load at the next current maximum down (57% from end 1), you can get over 6 watts total dissipation in the loads by making each load 50 ohms. And at that, they do a poor job of suppressing the current. This is a very crude example of a poorly designed "distributed balun", where the dissipation is high and the current suppression poor.

Now, the amount of dissipation illustrated here is insignificant in terms of signal strength loss, and I suspect that this is usually true. That is, even a poorly designed and/or placed resistive balun is unlikely to cost you any signal strength. But the dissipation can easily produce unacceptable heating of the balun. Also, the fact that the current is high enough at the balun location to cause substantial dissipation means that the balun isn't doing its job as it should -- the whole purpose is to reduce the current to a low value.

Hi Mike

Lots of possibilities here. Dont know if the following will help;

- The higher and clearer any external antenna you use the better it will work. Of coure you only need get adequate signal for it to work.
- Coax/transmission loss is a large problem on cellphone frequencies for long runs. I cant really give a quantitative answer here but dont run more than (say) 15ft of cable if it is 1/4" in diameter.
- The carriers in Oz quite often give publish site and coverage maps. From them it is often easy to determine which direction the base stations lie in. This will give you a rough indication of where to "point" an antenna or at least what side of the house to put it on.
- Going out and buying a cellphone antenna and simply moving it around looking for a strong signal might work. Problem is different carriers may have very different frequencies. There are also a lot of crap cheap antennas out there! Although an antenna can be made to easily to cover one band (say 950MHz odd) it requires a good design to cover two bands effectively and in your case with useful gain. Personally I'd have a play with a wideband gain antenna like a helix or maybe two corner reflectors (for the 2 freqs).
- Having three users on one antenna is also problematic. Lots of techie ways to do this but you may like to consider a passive repeater (an antenna inside the house that you hold the phone close too, joined to another outside the house with some coax) To be fair there have been NG posters who have mentioned that it never seems to work, but it has for me and is used in some of my works commercial installations.
- Cellphone coverage never covers everywhere. A valley is a pretty bad place if there isnt a base station mounted nearby. If your provider uses GSM there is also a 32km odd maximum distance you can use it from the base station. I am not suggesting it will work up to 32km. It just wont work past it even though you may see adequate signal in test mode. The answer in Australia where there is a lot of area not covered is to use a satphone, with the associated higher cost.

Apologies for not giving you a definitive answer. If I was tackling the problem I'd list where the nearest sites were for each carrier and what freqencies they were using. Then I'd throw together a quick antenna of theoretical dimensions (maybe an extended double ZEPP - I wouldnt bother tuning it) and make some hard measurements on various places on the balcony. From that I could determine if higher gain was needed and whether I could use the passive repeater system.

Cheers Bob VK2YQA

Hi,

A young reader (a CBer converted to ham, 16) sent me an email after have read my article about longwire and ask the next question.

As I haven't much experience with sloper, could some one give me some clues to help me solving his problem ?

Here is the case.
He uses a 15m long wire place to the south made of #18 AWG protected with a PVC jacket tight between a balconery close (2m) to his transmitter placed just in front of his window. The end of the sloper in attached on a fence without insulator located at the end of is garden. RTX side the antenna wire enter directly in the antenna input.

He works on 40 and 20m only and what to use the 75m also in SSB and CW. Read on an external SWR-meter, he get SWR 4:1 minimum and even almost infinite most of the time and can thus work on the air (or with at least 10W out on 100 PEP) and experiment much small electrical discharge...

Up to now I tell two things:
- For the discharge, I asked him to see this happened while transmitting or all the time. If that was while transmitting (but in all cases too of course) he has to see if his RTX was well AC grounded (to the mains ground or any plumbing system...)
- For the SWR I told him that it was due to a mismatch between the antenna impedance and the RTX and that he should use a coax longer that lambda-4, thus over 10m long to solve this (I don't speak about the Twin-Lead for transmission or the ladder line as it requires to cut the sloper in two).

Question:
This question interest me too. Is there another reason to get a very high SWR using a sloper such a way, without ground and connecting it directly to the RTX antenna jack (I think e.g. to the proximity of the house wall, the end not terminated (but looks usual) a coupling with the hosue wiring or the fence...). Is there other way to feed it excepting the coax ?
NB The inverted-V seems not to be a solution due to the too long extend of the ladder line and the V that will invade his neighbour property.

Thanks for comments

It's very easy. If you want to get rid of a majority of the BS, just add the
following filters:

From field: 'wa8ulx@aol.com' or 'w4nti@getridofthismindspring.com' (the 2
biggest spamfags around)
Subject field: 'wa8ulx', 'w4nti', 'bruce', 'brucie', 'dan', 'cbplusser',
'nocode', 'no-code', 'no code'

The newsgroups will be very different for you!

961. S - Y Parameter conversion with Smith Chart

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-30 15:49:41 UTC
From: Paul Burridge <pb@notthisbit.osiris1.co.uk>
Message-ID: <31rkg09gnprvh4idtll2jjdc53ghlpts43@4ax.com>
Source record: 91782
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur,rec.radio.amateur.antenna,sci.electronics.design

Hi guys,

I see in Chris Bowick's book on RF circuit design, he provides 8 quite long-winded formulas for converting between S and Y parameters and vice-versa. I'm always prone to making careless errors (particularly with signs) with these kind of equations, so I was wondering if there's a simpler, graphical method for conversion using the Smith Chart. After all, that's what it was devised for - the elimination of computational errors in such calculations.
I've tried using the vastly simpler rectangular/polar co-ordinate conversion formulas, but they don't plot correctly on the Smith Chart, it seems.
So, does anyone know of a simple graphical way to do it on the SC?

Thanks,

p.

Hi Thierry,

Add an insulator at the fence (probably won't change anything, but
still good design).

>He works on 40 and 20m only and what [wants] to use the 75m also in SSB and CW.
>Read[ing] on an external SWR-meter, he get[s] SWR 4:1 minimum and even almost
>infinite most of the time and can thus work on the air (or with at least 10W

Notice the harmonic relationships 20/40/80 - one or two may be a
problem for anyone.

>Up to now I tell two things:
>- For the discharge, I asked him to see this happened while transmitting or
>all the time. If that was while transmitting (but in all cases too of

>- For the SWR I told him that it was due to a mismatch between the antenna
>impedance and the RTX and that he should use a coax longer that lambda-4,

But he is not using any coax, right? Wire extends from rig to fence
with little room left over. So using coax does not seem to be part of
the original design, thus more coax is not an answer.

>thus over 10m long to solve this (I don't speak about the Twin-Lead for
>transmission or the ladder line as it requires to cut the sloper in two).

Adding length shifts the load Z, but will make the problem appear on
one of the other bands. Remember, you have the harmonic relationship
of 20/40/80.

The problem of arcing comes from the transmitter seeing a Hi-Z load
and for the power it is trying to put into it, the load transforms to
Hi-Voltage. Your friend's antenna runs from the transmitter's output
to the far end of the garden so there is no room for more transmission
line because there is NO transmission line in the first place.

The answer is to change the Hi-Z to a Lo-Z. Add a second wire that is 10M long. Connect it at the same point as the 15M wire at the transmitter. Hang the far end of the 10M wire at 10cM below the 15M wire. If there are still problems, add a third wire, 5M long. Hang the far end of the 5M wire at 10cM below the 10M wire.

Buy (or make) and use a tuner.

Have you actually measured it? I am trickle charging a riding lawn mower battery with an AT&T 12V phone brick. Open circuit voltage is 16, and current at 14V is about 2 ma. Kept the battery charged all winter long. This is a large battery, about 20#.

> Instructions for trickle-charging batteries inside MFJ antenna

Do you have a regular 13.8V station power supply. That is more than 13, though it seems like too much to leave connected to 10 nicads for any length of time. You could use a series resistor to make the charging rate lower.

Once upon a time in the 60's I decided to build one of these things. It
rquired a home made coil with oscilator of similar freq to yours. I in my
youthful wisdom decided that instead of winding the ciol to use a couple of
coils from an old radio and just run them at different freqs. Sounds like a
good plan. Wrong. Change this parameter and you will have to redesign a
large part of the thermin mostly because the oscillator will respond much
differently to changes in hand capacitance.

There is a section in the ARRL Antenna book, or the Manual, that describes
how you can use 75 Ohm cable to look like 50 Ohms. As I recall, you need a
very short piece (~Lambda/4) of 50 Ohm line in there somewhere.

Hi Mike

I think the cellular companies have some type of small or mini cell station unit to cover dead areas.

The reason I say this is, have you ever been in a store that sells cellular phones where you DIDN'T get a full strength signal while in the store?

Yet you go outside the store and drive 1/2 mile in any direction and your back in a dead area again. It's like the store itself is a small cellular tower that exists in a known dead area.

You can find online the location of the cell towers for each service in your area, along with the known dead zones in that service area.

Find a cell store in that dead zone and you will find you have a full signal as you near the store and inside the store itself.

I Wonder Why?

The only logical answer is, they have a mini tower at the store itself!

The range of a cell phone is very short, so I was very surprised that such a service ever got off the ground in the first place. Look at the grid of towers it takes to support it!

Seems low orbit satellite would have been the better route to take!

967. Is this wire 75 ohm twinlead?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-30 17:54:09 UTC
From: John D <jawnd393@yahoo.com>
Message-ID: <5XvOc.82$UN2.3@nwrddc02.gnilink.net>
Source record: 91788

I'm a new ham and this will be used for my first antenna.

I have 97 ft of twinlead that I think might be 75 ohm but there is no
identifying label on it.
I have searched the web and can't find any information on 75 ohm twinlead.
Can anyone identify this wire from these dimensions?

Conductors about 28 AWG. (7 strand of #34 or 35) .
Separated about 1/4 inch apart.
Width overall .361" x .125 or (almost 3/8)"
Thickness overall 1/8"
Web thickness .035"
Each wire has some white insulation around it and the outer twinlead shaped
insulation is black

This wire is very light and I want to use it to feed a HF dipole with no
center support.
My maximum power is 200 watts.
John

Paul

I used to think I could do alot of things with Smith Charts and Z theta
Charts. I'm way out of practice, but might be able (and willing) to point
you to where you can solve the problem you now have.

Since I am not smart enough to see *exactly* whats involved with S and Y
in your post, I may be off base with this. -- Are you aware that the
admittance of an impedance can be identified by overlaying a transparent
Smith Chart over another Smith Chart with "zero" impedance overlaid on
"infinite" impedance.

Arnie

Forgive me if you are joking and I'm so dense that I take you seriously.

When only the outer conductors of two parallel coax's are connected, the
impedance between each center conductor to that junction is ~75 ohms.
Between the two center conductors the impedance will be the series of the
two unbalanced 75 ohm resulting in a 150 ohm balanced line.

That's interesting -- I just measured the MFJ-1312D wall wart, which
is rated at 12 vdc/500ma -- it measures close to 18 volts. The
instructions say the 269 will operate with any voltage between 11 and
18, with 14.5v being ideal.

Actually, I do have a 13.8v station supply with a plug that will fit
the 269. The instructions for the 269 say the internal trickle charger
needs between 14 and 18 volts to operate properly, and no less than
13.

Looks like I actually have a couple of ways to go, in recharging the
batteries.

So did Motorola, about 15 years ago. It created the Iridium system, which is exactly that. It works like a cell system, except it's the cells -- the satellites -- that move. It was such a commercial failure that the subsidiary declared bankruptcy. (A 1999 commentary about its problems can be found at http://partners.nytimes.com/library/tech/99/09/biztech/articles/07iridium.html.) It was within days of bringing the satellites down when a consortium of investors bought it and have apparently made it economically viable. You can get more information at their web site, http://www.iridium.com.

Hi Richard,

I like your suggestion, do it... but that 'd change anything !... ;-)
For sure I will ask him to isolate it.

What is the principle hidden behind this additional wire ? And why 10m or
shorter ?
Does it play the same role as a lambda-4 coax to match the Z ? Strange...

I though first adding also a 2d wire, but like a dipole (instead of cuttinh
his longwire in 2 parts), and to feed it by the center using a 75-ohm
Twin-Lead (for transmission).

Does it alter the property of the longwire to feed it using a coax or a
twin-lead ? it is however a convential method isn't it ?

That said, after a quick read I take exception to what you say below
and in the antenna notes about current "induced" in the "simulated"
coax. Unless I'm missin' something, this antenna is totally
symmetrical about the z-axis, so how current is induced is a mystery
to me. I can see where the "conducted" current comes from, you have
two wires connected end-to-end with a source on one of them. I call
this an "antenna". [g]

Later.

Wes

|I'm not sure you can extrapolate this to the problem at hand. For an
|illustration, open the EZNEC model VHFGP.ez, and add a wire from 0,0,5
|to 0,0,3.25, 40 segments. This will behave like a more-or-less worst
|case transmission line. You'll see that there's substantial current on
|the new wire, with a maximum at the top -- where it connects to the
|ground plane -- and cyclic loops of current along its length. At about
|1/4 wavelength from the top, the current is very low. Insert a load at
|that point (14% from end 1). You'll see that a low impedance at that
|point isn't transformed to a high impedance at the top of the wire. In
|fact, it doesn't matter hardly at all what impedance you insert at that
|point -- it has very little effect on the current at the top. This
|shouldn't be a surprise, since elementary circuit theory tells us we can
|insert any resistance at a point of zero current without upsetting
|anything. A resistance at the top of the wire, though, will reduce the
|current at that point.
|
|Now set the power to a constant value, say 100 watts, via the Options
|menu, and look at the power dissipated by a load inserted at the top of
|the wire (wire 6, 0% from end 1). Maximum dissipation (about 2 watts)
|occurs with a load resistance of about 100 ohms. The current at that
|point is minimized with a high resistance, although it doesn't have much
|effect on the current on the rest of the wire beyond about 1/4
|wavelength from the top. In this interesting case, you need a balun at
|an odd number of quarter wavelengths from the bottom of the wire to
|suppress the induced current, and another at the top of the wire to
|suppress the conducted current.
|

|Put a single load about a half wavelength from the top (29% from end 1),
|at one of the current maxima. You'll find that you can get up to nearly
|6 watts dissipation in the load (seen by clicking Load Dat) by varying
|the load resistance, with the maximum at about 100 ohms. If you add a
|second load at the next current maximum down (57% from end 1), you can
|get over 6 watts total dissipation in the loads by making each load 50
|ohms. And at that, they do a poor job of suppressing the current. This
|is a very crude example of a poorly designed "distributed balun", where
|the dissipation is high and the current suppression poor.
|
|Now, the amount of dissipation illustrated here is insignificant in
|terms of signal strength loss, and I suspect that this is usually true.
|That is, even a poorly designed and/or placed resistive balun is
|unlikely to cost you any signal strength. But the dissipation can easily
|produce unacceptable heating of the balun. Also, the fact that the
|current is high enough at the balun location to cause substantial
|dissipation means that the balun isn't doing its job as it should -- the
|whole purpose is to reduce the current to a low value.
|

You are missing something. The added wire is collinear with both the vertical radiating element and the vertical component of the ground plane radials. There's finite mutual impedance between collinear conductors, hence mutual coupling. If you need proof, change the coordinate of the top of the added wire to disconnect it from the antenna and run the simulation. You'll get maximum current on the added wire when it's approximately an integer multiple of a half wavelength long.

A feedline placed symmetrically with respect to a conventional dipole doesn't have any net induced current because the coupling from each half of the dipole is equal and opposite to the coupling from the other half. That's not the case with the ground plane example, where the coupling from the vertical wire is different in magnitude and not opposite to the coupling from the radials.

Sorry, I should have mentioned that. Most wall warts are poorly regulated, so one that's rated at 12 volts will commonly produce higher voltage at lower than its rated current, and anywhere from 15 to 18 volts open circuit. So a 12 volt wall wart with current rating well above what you'll be drawing (70-100 mA for a 15 hour AA NiCd charger) should work fine.

Hi Thierry,

Think about it. You have a Hi-Z antenna at 15M. You have a lower-Z
antenna at 10M (or 5M). What is Hi-Z in parallel with Low-Z?

This is called a "Fan" design (because the wires are spread out like a
japanese fan to keep the wires apart - it doesn't take much). With a
"Fan" design, the frequency driving all the wires will guarantee one
wire will be Low-Z and the power will go there because this Low-Z wire
"shorts" out the others.

>Does it alter the property of the longwire to feed it using a coax or a
>twin-lead ?

No. An antenna is an antenna, a transmission line is a transmission
line. Together they are a system. Yes, you are changing the system,
but the parts remain working in their own functions. When you change
the system by altering a part, the system response changes (Z). The
antenna still radiates (and the transmission line should not - unless
something is broken).

> it is however a convential method isn't it ?

Conventional yes, but your friend is not doing conventional.

Bob

If you decide to mahe your own charger, you might want to consider using a
light bulb in series with the voltage source. That can be a way of limiting
charging current.

Since I dont know what kind of batteries are being charged, it is
incorrect for me to advise anything about the charger.

Jerry

Jim

I'm kinda embarressed to admit that I'm not even sure what Y and S refers to. I do remember that impedances plotted on a Smith Chart will follow the lines of constant "conductance" on the transparent overlay. Maybe thats too fundamental for inclusion in this thread. But, it sure is a quick way of predicting how much shunt Xl or Xc is needed to "tune" to a more desireable impedance.

Yup and you can get one with the admittance chart already overlaid
on the impedance chart. any point plotted can be read either way and
the s-params are also directly read from either with dividers or a
ruler.

I have no clue why Paul is converting between rectangular and polar
and replotting. The point should stay put.

Indeed. And that is something I've considered. But The way Bowick
explains it, it *ought* to be possible to perform the conversion
summarily by a simple graphical method. Unfortunately, the
arithmetical method he describes only works for linear polar charts,
which of course the SC certainly isn't linear!
And the guy who suggested the 180' rotation: I reckon that's *part* of
the solution, but simply doing this alone merely converts impedances
to admittances. S-params are typically denoted in the form x+/-yj
whereas the Y-params are denoted as vector and angular co-ordinates,
so further mappings and/or translations are required following any
rotation...
Still, I'm sure someone out there will know. :-/

Paul

I realize that I dont understand what needs to be done. I'm just too far
out of touch with technology. But, is there any chance that a Ztheta Chart
overlay would be of any assistance?? Properly used, the combination of
Smith and Ztheta can be a usefull tool. That overlay provides the impedance
magnitude with its angle, at a glance, for all R+/- j X.

Hi Richard, I use a fan-design on one of my "long wire" antennas (which is fed from the ground-end across 1/2 of a 4:1 current balun, other half is grounded, an arguably less noisy design but it does work). And I'm about to add another, which an ATU will assist across 2-16mhz.

My question is, do you recommend a particular method of joining the "fan" ends together at the balun? Twisting them together in a haphazard fashion with a doping of solder and coax-seal might be electrically inferior to a splice or other connector design. Any thoughts?

Yes, do a Google search on "Smith Chart" and you can get several freeware or demo versions of the Chart that will do exactly what you want. I use a demo version of a Smith Chart program that is amazing. Very easy to use and it is free. Look around, it is out there.

Jerry, I appreciate your tip. But that's not actually what I'm trying
to ascertain. The complete SC is hard enough to read as it is without
overlaying a spherical grid on it! Your idea might well work, don't
get me wrong, but I just need to know if S-Y mappings can be carried
out with the Smith Chart *alone.*

Thanks,

Paul

So the message I'm reading is that Cushcraft antenna's are no more than a wet noodle.

How much percentage increase in QSL's in the box would one expect to expect by changing from a Cushcraft to a computerized optimal yagi of your choice of the same boom length, same height, same feedline, etc?

After all, Q's in the book is what it all boils down to. If one works say 100 grid squares in 6 months, could you expect to work 110 grids (10% increase) ? 125 grids?

I know I sure could use more front to back ratio ... those EN67 guys are really making it hard for me to get those last grids in FL !

Semiconductor s-params are usually listed as magnitude and angle, with
the mag sometimes in pure scalar form, or sometimes in dB. A universal
conversion program would be nice, espacially if it included equivalent
reactance, capacitance, inductance, stuff like that.

Hi Jack,

Joins of metal should always be bright to bright metal. Pressure on
joins will break the oxide coating, but a relaxing join obviously
allows corrosion. Hence you solder. Solder is a sealant, not a
mechanical splice. If you can guarantee the pressure (like using a
household AC splice or automotive splices), you can tape it, or use
coax-seal. Make sure that tension of hanging does not weaken the
pressure seal because metals will flow. Aluminum has a habit of what
is called cold flow, it relaxes from the installation pressure. You
need industrial splices for them. Also, dissimilar metals will
corrode through cathodic potentials (reduction). There are also
industrial splices for dissimilar metals.

The sturdiest mechanical splice is called the "Western Union Splice"
use a search engine for illustrations.

I can't give you hard numbers, but often it's standing out in the pileup
just that little bit more that counts; you get that Q done sooner, and
can move on to the next grid you need sooner. Also a better pattern and
gain will let you hear better a lot of the time. And when running weak
tropo, and extra 2 dB gain can make the contact you would have lost. In
the short run not a great difference, perhaps, but in the long run it's
extra Qs, Especially valuable in a contest.

The ARRL Antenna book says the Zo of a two wire line is Zo=276 log (2S/d) ohms.
S is the center-to center wire spacing, and d is the diameter of the wire plus
insulation. Sorry I don't have the time to calculate your Zo, maybe later.

I sense some confusion about s and y parameters. S parameters aren't impedances -- they're dimensionless transmission or reflection coefficients. They do have a real and imaginary part (or magnitude and angle) like an impedance, but that's as far as the similarity goes. You can overlay a Smith chart on a polar plot of reflection coefficient (e.g., s11) and directly read the normalized impedance which causes that reflection coefficient. But what you read from the Smith chart isn't the the reflection coefficient -- that is, it's not the s parameter. When you reverse the Smith chart, you get the admittance causing the reflection coefficient, but this still isn't a y parameter. If you invert an s parameter, you still have a dimensionless number.

Y (admittance) parameters are a different critter, are measured differently than s parameters, and have the dimensions of admittance. Transformation from s to y or vice-versa isn't simple. For example,

y11 = {[(1 - s11)(1 + s22) + s12s21] / [(1 + s11)(1 + s22) - s12s21]}/Z0

(See, for example, Gonzalez, _Microwave Transistor Amplifiers, Analysis and Design_.) From this you can see that in order to find y11, you not only have to know s11, but also s12, s21, and s22. So it's simply not possible to convert from y11 to s11 if s11 is all you know.

> 73 Gary N4AST

d is the diameter of the wire, period. The formula is for a line with no insulation. If the whole electric field is in the dielectric (as it is in coax), the impedance is modified by a factor 1/sqrt(erel) where erel is the relative permittivity (dielectric constant) of the insulation. 1/sqrt(erel) also happens to be the velocity factor in a line where the entire field is in the dielectric. For polyethylene, 1/sqrt(erel) is about 0.66, so the characteristic impedance of twinlead line with polyethylene insulation between conductors (where some but not all the field is in the dielectric) is somewhere between the value calculated from the formula and 0.66 times that value. You can measure the velocity factor by a number of methods. If you know the velocity factor, the impedance is the formula value times the velocity factor.

I want a simple AM Antenna to connect to my hi-fi system.
I really like AM but I cannot access it at the moment.

Does anyone know where I could get an AM Antenna for a Hi-Fi in Australia

Regards,

Robert.

Bullshit. it's magnitude and angle. You plot Z = R + jX on the
friggin chart and measure the distance from the origin to get
magnitude. You measure the angle to get.. angle. Imagine that.

If you do mag = sqrt(R^2 + X^2) and angle = atan(X/R) and plot it,
you'll see that no conversion was necessary at all.

J.W., well, lets put it into context-- the Cushcraft 5 EL yagi Works
(but it it is NOT an optimum preformer: Calcs to the following specs:
7.58 DBd Gain, for your 11.8 foot long yagi-- if optimized, would run
8.0 DBd (f/b, respectavely , 9.95 DBd, optimized, would do 22.1 dB F/B)

Now, here are couple others (Because of constraints of time):

a homade 5 el yagi, with 17.6 ft long boom (yes, only 5-1/2 foot
longer), that would provide 11.39 DBd gain, , with a 25 Db f/b ratio

Or: a 4 el, yagi, that is 13 ft-2 inchs long (Gee, only 1-1/2 foot
longer)! with 8.47 DBd gain, and 23 DB f/b ratio, or, another 4 el
yagi, again for six, this 13 ft-8 inchs (2 foot longer), provides 8.91
DBd Gain, and a F/B of 19.45 Db !!
Now, granted these calculated gains in free space, and wont boor you
with the importance of Db , other than to try to patiently explain that
these are EXPONENTIAL (10 DB= 10 X the POWER, 20 DB= 100 x power, 30
DB= 1000 X Power, ect), nor trouble you with the FACT that when 6 is
dead, its DEAD- except for Tropo SCATTER!, and that in weak DOUBLE HOP
openings, the difference between low power, and/or antenna (Gain/Loss),
and a KW, with SERIOUS GAIN is often the difference between Q's, and
DEAD SILENCE! If you wish to work the limited openings, then, you are
ideally set up-- For a SERIOUS DX station, for six, GIVE IT UP, or get
MORE HORSEPOWER! (Hint: if you can be heard CONSISTANTLY,and hear them
600-1200 miles away, when you key up by other Serious stations, (and
like W7GJ, W6YKM, N7ML, K5CM, W5FF, N5JKV, Ect. Then you are getting
there- But remember, anyone when the band opens can work multitudes of
dx-- If serious, tho, remember mederocre dont get it! Jim NN7K

Lots of possibilities here...

How about a longish piece of wire attached to the terminal and another
from the ground terminal (if any) to "real ground"?

Or maybe wind a loop antenna on a smallish (say 8") former?

You might be able to get a ferrite bar antenna from places like Wes
Components...

There isnt anything critical about a AM broadscast receive antenna! If
noise is a problem you may need to take some more time with it...

Cheers Bob VK2YQA

My Adcom am-fm tuner/preamp came with a small AM loop that attaches to
a clamp on the back of the chassis. You might look at what type of AM
connector your hi-fi has, and then check for something from your
nearest hi-fi dealer.

****
Well, I'm no math whiz but I get 392 ohms or x.66=259 ohms
(2 x .25) / .019 = 26.31 , 26.31 press [log] gets 1.42, 1.42 x 276=
392, 392 x .66=259

So maybe its just some skinny 300 ohm twinlead

I tried the same formula for some known 300 ohn twinlead and got 387 to 255.

1016. Icom AH-4 Placement and Really Cold Weather

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-31 04:40:33 UTC
From: asaciuk@hotmail.com
Message-ID: <507b07c2.0407302040.2750099b@posting.google.com>
Source record: 91737

Hello!

I've been thinking about buying an Icom AH-4 Tuner, to run multiband on an end fed antenna. I was hoping to place the AH-4 as near to the roof as possible, as the end fed is going to run from the roof peak of the back of my house, to a large tree in the front yard (too many wires, hydro poles and accidents waiting to happen in the back).

Now here is the problem... Our winters north of the 49th often reach temperatures of -35 celcius for weeks on end, which according to the literature, are beyond the AH-4's tolerance of -10 celcius.

What would be the easiest solution? The attic naturally gets as cold as outdoors, so I can't stash the tuner in the attic, and run the wire out. I don't know about putting the tuner in the closet to run a single wire through the wall and out, as I want to get the transmitting wire high up, and as far away from myself as possible. I have an Icom 746, so I was hoping to actually use full power (100 watts) and feel comfortable about keeping the AH-4 at a reasonable temperature, and yet not rearranging my DNA while I transmit.

Any suggestions would be greatly appreciated

73,
Andrew

Roy,

Thanks for another well informed and sensible reply.

Paul,

Why limit yourself to going from S to Y parameters. Might as well go for H and Z parameters too.

If possible, find yourself a copy of HP Application Note 154, April, 1972 "S-Parameter Design". In the first few paragraphs they point out that H, Y, and Z parameters are defined by voltages and currents.

Quoting:

"The important thing to note here is that both open and short circuits are essential for making these measurements.

Moving to higher and higher frequencies, some problems arise:
1. Equipment is not readily available to measure total voltage and total current at the ports of the network.
2. Short and open circuits are difficult to achieve over a broad band of frequencies.
3. Active devices, such as transistors and tunnel diodes, very often will not be short or open circuit stable."

So, since the 60's, RF designers have been using S-parameters to characterize devices and circuits. They are based on reflection and transmission in a 50 ohm system. They are measurable. Why do you feel you want to use Y parameters? (Why-oh Y-oh?)

It all depends on your attitude towards DX.

The easy QSOs were always going into the book - any antenna would have hooked them. This is especially true with 6m summer E-skip.

But what about the ones that DON'T get into the book? The ones you can't quite copy; the ones who can't quite copy you; the pileups you fail to break; the contest multipliers you fail to score... the ones you really wanted.

Very soon, it's the QSOs you DON'T make that really start to matter. And then you start to think, and can be heard muttering things like...
>I know I sure could use more front to back ratio ... those EN67 guys
>are really making it hard for me to get those last grids in FL !
>

If such things bug you, then beware - you're in danger of becoming a serious DXer.

Casual DXers are probably happier people, but don't let them tell you that those last few decibels "don't matter." If they matter in *your* kind of amateur radio, then they *are* important.

Sounds like Radio-Shack 300-ohm weatherproof twinlead.
solder a 50-ohm resistor across the wires and hook up a MFJ 259
I've used 300-ohm twinlead - because it was cheap and low-loss(no flames
pls) - but I wound 4-to-1 baluns for use on both ends . I could live with
1.5 swr

OR use it to feed a G5RV - without baluns - or should I say as 'part-of' a
G5RV

ITs ok to use 75-ohm coax - 1.5 swr is acceptable - right? so why try to convert it

Not to argue, but you might want to look up AM (amplitude modulation)
The AM broadcast band is another matter.
If you have a 580 khz carrier you can turn it on/off (digital) - or - you
can modulate it (AM). - and I guess you could do both at the same time.
we use digital - (morse code) on the ham bands

OK - I see what they're doing - piggy-backing digital on top of AM - so
they're doing both at the same time
interesting - you need one type of radio for AM and another tyype to receive
the 'HD' signal

Yep.

> I tried the same formula for some known 300 ohn twinlead and got 387 to 255.

I've measured the velocity factor of some flat twinlead with fairly heavy insulation at about 0.8. 0.8 times your no-insulation value of 387 ohms is 310, so that's about right. By the way, don't expect "300 ohm" twinlead to be exactly 300 ohms, or even really close. The tolerance is very loose.

Source record: 91748

I have a 1.8m fibreglass rod from a 27Mhz whip, to which I have added braiding to make a 1/4 wave at 52Mhz.

Now, I still have a foot of glass left at the top and I'm interested in making it resonant at 10m as well. I understand how to make traps for a given frequency, but not how to calculate what that frequency should be in the case of a non-resonant trap.

As I understand it, a trap at resonance 'somewhere' between 29 and 52 Mhz can be added to a whip that will electrically lenghten it into resonance at 10m, and electrically shorten it into resonance at 6m.

What I don't understand is exactly how one calculates:
The traps own resonance
The equilant physical length of the trap at a given frequency, and
The lengths of the radiating segments, allowing for loading and mutual coupling.

I appreciate that some "real world" tweaking of the design is almost always required, but how is the basic layout produced? Is it possible to calculate in advance which combinations will work well and which won't?

>S-params are typically
>denoted in the form x+/-yj whereas the Y-params are denoted as vector
>and angular co-ordinates, so further mappings and/or translations are
>required following any rotation...

I don't know which way you want to convert, but the conversion from
magnitude and angle to complex Cartesian co-ordinates is:

x = mag*cos(angle), y = mag*sin(angle)

Be careful of the signs of sin and cos if angle is negative. sin is
negative and cos is positive. You can see this if you draw a simple
diagram of x and y axes.

To convert the other way,

mag = sqrt(x^2 + y^2), angle =arctan(y/x).

This isn't difficult mathematics in these days of scientific
calculators, but you do need to be careful about signs, AND check that
the result is credible: if it isn't, you probably made a keying error.

For example, when you calculate angle, then calculate its sin and cos,
to check with the original data.

Hear! Hear! Thank God there are still some folks here who know what
they're talking about.

[snip]
>So, since the 60's, RF designers have been using S-parameters to
>characterize devices and circuits. They are based on reflection and
>transmission in a 50 ohm system. They are measurable. Why do you feel
>you want to use Y parameters? (Why-oh Y-oh?)

I agree entirely, Rex. I'd much sooner use scattering parameters alone
for the reasons given in your post. The only flY in the ointment is
that some datasheets only provide Y-params and when those times arise
one needs to be able to convert between the two. Now it transpires
from what Roy has stated that there is no feasible way to convert the
two using the Smith Chart. That's fine; at least I know I'm not doing
all that mathematical manipulation unnecessarily. John L's suggestion
of writing a routine to do the fiddly bits now seems the most likely
solution. Should only take about a line-and-a-half of C++.
Thanks, both.

I read in sci.electronics.design that Jerry Martes
<j.jmartes@verizon.net> wrote (in <fcCOc.467$Je5.431@nwrddc03.gnilink.ne
t>) about 'S - Y Parameter conversion with Smith Chart', on Sat, 31 Jul
2004:
> I just now learned about S and Y parameters. I learned that they are
>WAY too complex for me to understand. I think it *is* time for me to
>apologize for commenting when I could have been more help by remaining
>silent.

I suspect that in fact they aren't too complex for you to understand.
There are lots of over-complicated explanations around. The Y
(admittance) parameters relate the input and output currents to the
input and output voltages, using the basic equation (Ohm's Law V = IR
inverted) I = VY.

Because there is internal feedback and feed-forward inside the
transistor, the output voltage has an (unwanted, usually) effect on the
input current and the input voltage has a wanted effect on the output
current. For this we get two not very difficult equations:

Iin = VinYin + VoutYfeedback

Iout = Vin Yfeedforward + VoutYout

The suffixes are often replaced by two numbers, where 1 means input and
2 means output.

I in = I1, Vin = V1, Iout = I2, Vout = V2.

Yin = Y11, Yfeedback = Y12, Yfeedforward = Y21, Yout = Y22.

S parameters deal with how well the input and output impedances match a
specified characteristic impedance, usually 50 ohms, and are based on
incident and reflected powers.

In the general case, the possibility appears to be allowed of applying
power at the output as well as, or instead of, the input. Normally, of
course, this isn't the case; the 'output power' flows out of the device
and is what you want!

Pina is the power applied to the input and Pinr is the power reflected
(if the input impedance doesn't match the chosen characteristic
impedance). Pouta is the power produced (or applied) at the output and
Poutr is the reflected power at the output (if there is a mismatch).

Using the numbers 1 and 2 as explained above:

Pinr = S11Pina + S12Pouta

Poutr = S21Pina + S22Pouta

Again, these are not very difficult. However, some of the calculations using them can be a bit more complicated, but don't use any mathematical concepts more advanced that square roots, sin, cos and tan, and x + jy.

There is a paper in Electronics, October 16 1967, 'Quick amplifier design with scattering parameters' by William H Froehner (then of TI), which gives a lot of useful information, and a reference to a previous, simpler paper. I only have a monochrome photocopy, and some of the diagrams use colour, but it may be possible to retrieve the original through a library service.

I read in sci.electronics.design that Roy Lewallen <w7el@eznec.com>
wrote (in <10glmf6regc7re4@corp.supernews.com>) about 'S - Y Parameter
conversion with Smith Chart', on Fri, 30 Jul 2004:

>Transformation from s to y or vice-versa isn't simple. For example,
>
>y11 = {[(1 - s11)(1 + s22) + s12s21] / [(1 + s11)(1 + s22) - s12s21]}/Z0

It doesn't look too simple written in ASCII, but it only uses addition,
subtraction, multiplication and division, with brackets [1]. It's a bit
easier to understand if you get rid of the double division by moving Z0
up-front, and write out the remaining division as a fraction:

$$y11 = Z0 * \frac{(1 - s11)*(1 + s22) + s12*s21}{(1 + s11)*(1 + s22) - s12*s21}$$

[1] OK, you need a few basics of phasor arithmetic:

If S is a phasor = magS,angleS and T is a phasor = magT, angleT, then:

S + T = (magS + magT),(angleS + angleT)

S - T = (magS - magT),(angleS - angleT)

S*T = (magS*magT),(angleS + angleT)

S/T = (magS/magT),(angleS - angleT)

To convert dBmagS in dB to magS as a number, magS = 10^(dBmagS/10). (/10
because the equations are about power, not voltage or current.

I understand that you don't understand that you can read Y, Z, and S
params directly off the chart. The only time you need the
conversions is if you don't have a vhart.

here's your OP:

"I see in Chris Bowick's book on RF circuit design, he provides 8
quite
long-winded formulas for converting between S and Y parameters and
vice-versa. I'm always prone to making careless errors (particularly
with signs) with these kind of equations, so I was wondering if
there's a simpler, graphical method for conversion using the Smith
Chart. After all, that's what it was devised for - the elimination
of
computational errors in such calculations.
I've tried using the vastly simpler rectangular/polar co-ordinate
conversion formulas, but they don't plot correctly on the Smith
Chart,
it seems.
So, does anyone know of a simple graphical way to do it on the SC?"

So turn to page 106 and notice that an S param is plotted and if the
light and your eyes are good enough, you'll see that the point is
also labeled 2 + j1.5

Now what's with the learning disability?

> If you don't have anything useful to contribute to the

Motorola also has a couple ANs on "amplifier" "design" and
"impedance matching". Keywords would be those quoted above and
"Linvill".

Well so? Since you think you know better than everyone else here,
perhaps you'd like to tell us how to convert this S-parameter, plotted
on the chart as you say as 2+j1.5 to its Y-parameter equivalent
without using the conversion formulas shown on P.107? For the
avoidance of doubt: show us how you would derive the equivalent
Y-parameter for 2+j1.5 by the use of the Chart alone.

>I just did. Twice. Don't jump my ass just because what you heard is

1039. Update on DLM Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-31 12:19:04 UTC
From: fractenna@aol.com
Message-ID: <20040731081904.04588.00002232@mb-m10.aol.com>
Source record: 91760

Mr. Robert Vincent's/ University of Rhode island (URI) "revolutionary, new" DLM antenna technology has experienced some public informational updates. In particular, I suggest the following URL:

http://www.uri.edu/research/tro/NCD_for_Tape,_040604.html

As I have stated previously, I am of the opinion that the issue of 'new' and 'revolutionary' may not be accurate when considering the prior art relative to Mr. Vincents' 'DLM antenna technology'. In support of this, I have purchased an antenna which appears to be predominantly marketed to CB'ers and truckers, although it also can be used by hams. The manufacturer's statements closely match Mr Vincent's claims with respect to efficiency, bandwidth, and size. It is not the Midland antenna I alluded to earlier. As the company has had the product out for several years--according to the sales department-- it is unlikely to be a licensed Vincent DLM antenna (many years is not 'new'). The manufacturer appears to represent the antenna realistically, in my opinion, and does not pose it as 'revolutionary', to my knowledge. Instead, the manufacturer has apparently found an appropriate niche with CB truckers.

I will provide additional information coinciding with the oral public discussion of the Vincent DLM antenna in mid-August. I will personally conduct range measurements on this commercially available antenna--which is clearly a distributed-load monopole. This is a technical fact: It is loaded, and it is not contunuously loaded: the load is distributed. I have already secured a URL for reporting these results, if needed.

It is important at this point to understand that Mr. Vincent's claims of 'wide in bandwidth' allude to 3-5%. In comparison, a dipole exceeds this value. Most skilled in the art would not refer to 3-5% bandwidths as wideband. It is also important to understand that antenna(s) with similar claims of similar bandwidth, at high efficiency, and 1/3 the regular size is (are) available on the commercial market. It will be interesting to see if the Vincent DLM antenna technology is better than something else already available to CB'ers, for example. I am of the opinion that this will not prove to be so.

73,
Chip N1IR

> calculate in advance which combinations will work well and which won't?

Well, you almost have it correct. The trap should resonate in the middle
of the band you wish to operate. For example, if you wish to operate
from 28 to 29 MHz you would resonate the trap at ~28.5 MHz.

The idea behind the trap is that, at resonance, 28.5 MHz, it provides
a low impedance to your signal and connects through to the extra wire
that is past the trap. At 52 MHz the trap would present a high impedance
and effectively isolate the extra wire from the rest of the antenna.

There are several varieties of traps. The most basic is the coil and
capacitor variety. Then there are several types of traps made out of
coaxial cable. I have found the coaxial type to be the easiest to work
with. For information on designing these traps get a copy of HamCalc.
The latest version can be had at

http://www.cq-amateur-radio.com/HamCalcem.html

There is a windows version at the following address but I don't know
if it contains everything that the original has in it.

http://www.vwlowen.demon.co.uk

I'll have similar information, but in a different format, on my own web site when I get the chance.

The method that I use to adjust a trap antenna is to start with the hightest frequency first.

1. Get the 52 MHz adjusted to the right length first, with no trap or extra wire added.

2. Using a grid-dip meter, adjust the trap for resonance. Do this without the trap connected to anything. You will not be able to check it's resonance once it is connected to the antenna elements. Fine tune the resonance by adjusting the turns spacing of the coil. Once you get it where you want it, secure the turns in place with tape or glue.

3. Add the extra wire and adjust the length for a reasonably low SWR on 10 Meters. The HamCalc programs will give you a estimation on the shortening effect of the trap.

If you don't have a grid-dip meter, try and borrow one from someone. For only a single use it wouldn't make sense to buy one.

You didn't say whether you are using this for mobile or base station use. What are you using for ground radials? For 6 Meters you should have several radials that are a little longer than 1/4 wave, at 6 Meters. To make the antenna load better on 10 Meters, add more radials that are a little longer than 1/4 wave at 10 Meters. I do it by using the same tie point at the feed but then I fan them out away from the antenna.

If I made any errors in this I'm sure that someone else will correct things. Good Luck.

So you replied before I could add to my last post, but...

> Since you think you know better than everyone else here,

I haven't contradicted anything that was said other than that which
you've said and no one has bothered to correct me on anything. Are
you also delusional? I should however take the opportunity to point
out that John Woodgate also mentioned that polar conversion, but he
did mention that it was for cartesian coords, which doesn't apply
to your current quandry.

notice that you alluded to using polar/rect conversions? That works
for finding going between admittance (mag, angle) and
conductance/suseptance. My head was still in the cartesian plane but
I can see why it didn't work for you.

BTW, I think if the data sheet gives Y params, I'd use 'em unless I
had another reason to convert to S-Params.

> perhaps you'd like to tell us how to convert this S-parameter, plotted
> on the chart as you say as 2+j1.5

2 + j1.5 is not an S-param it's a Y-param

> to its Y-parameter equivalent

You mean its reflection coefficient. Its magnitude is the length of
the line and its angle is, again, the angle. No conversion
necessary, it's a graphical solution. That's what you wanted and
that's what you got.

> without using the conversion formulas shown on P.107?

Did I say I could? ... Aside from my initial knee jerk polar/rect
conversion.

Those eqs look like the were derived from eqs for circles.

> For the
> avoidance of doubt: show us how you would derive the equivalent
> Y-parameter for 2+j1.5 by the use of the Chart alone.

You asked for a graphical solution and you got it. Twice or so.
>
>>I just did. Twice. Don't jump my ass just because what you heard is

No, only that one post and I had to use the term because you've had
enough time to memorize that book word for word and yet you insist
on confusing basic things with statements like:

"S-params are typically denoted in the form x+/-yj whereas the
Y-params are denoted as vector and angular co-ordinates"

Also, the post started with the abrev, "VB", not "bullshit".

>

Well, at least you'll have attached *some* value to it. Do you think
I can use it to reduce the Miller capacitance seen at the base?
Hmmm... "cap", "charge", and "input" in 2 lines. Sounds like an
electronics discussion. I thought you said that wasn't allowed here
in sed.

Hi Roy

I didn't know Iridian was low orbit satellite, I thought it was the bigger birds.

In the late 1960's I had a Motorola System in my car, darn thing took up most of my trunk space too.
At least we never had Dead Areas. Areas where we needed more power to get back to the station, but no dead areas to speak of, you could always hear along with the static of course.

My XYL at that time was a licensed ham also, so we could communicate at preset times when she would stand by the rig to see if I was calling her. It was just to expensive to make a call on the mobile phone. I just love the newer HTs of today with the coded tone squelch and the like, but my current XYL is not licensed and don't care to be either. I just can't get her interested in radio at all.

Actually, you would want the trap to resonate at 6M thus providing a hi Z
and making the whip beyond the trap invisible.

> The idea behind the trap is that, at resonance, 28.5 MHz, it provides
> a low impedance to your signal and connects through to the extra wire
> that is past the trap. At 52 MHz the trap would present a high impedance
> and effectively isolate the extra wire from the rest of the antenna.
>
Actually, at 28MHz the trap will look inductive thus shortening the overall
length for 10M.

A much easier solution is to simply use an inductive choke at the top of the
6M section and then an appropriate tip to resonate the antenna on 10M. Reg
Edwards site provides the information for doing this- in the form of
inductively shortened dipoles. The program allows one to place the inductive

load anywhere along the wire.

>Well, you almost have it correct. The trap should resonate in the
>middle
>of the band you wish to operate.

Not always. Matt knows exactly what he's looking for - he really does mean a trap that is resonant *between* the two target bands!

The parallel L/C circuit will appear inductive on the lower band, so it makes the antenna electrically longer; while on the higher band it appears capacitive and makes the antenna electrically shorter. The trick is to work out how to make the whole antenna resonant on both bands simultaneously.

The original idea was in 'Ham Radio' several years ago:
Designing trap antennas: a new approach by Yardley Beers, W0JF Aug 87 p60

Unfortunately I don't have the reference itself, but maybe someone here has either the magazine or a CD?

This antenna is much harder to design than a conventional system with resonant traps, because no individual part of the antenna is resonant on either band. It needs either a lot of cut-and-try, or a little help from a computer.

There might have been a BASIC listing in the original article, but I'd
bet that Reg could knock together a program before bedtime :-)

That's the pot calling the kettle black. Aside from the need for
others to repeatedly spell things out for you, you're also the guy
who braged about the record setting flame war you had with some
dude. I don't suppose yuo consider that a waste of bandwidth. Don't
add hypocrisy to your transgressionsl.

> by just simply stating "no it's not possible to perform a summary
> translation between S and Y parameters by mappings on the Smith Chart"

But for the third time, it is. The eqs are for getting a *numerical*
answer. If you have the chart, you just read the conversion off of
it directly. Start with the example on pg 105.

That's three (or so) times I've told you and yet you can't
understand why people tire of your lack of understanding.

> and we could all have got on with our lives.

Didn't know you had one ;) ... couldn't resist.

I'm thinking about putting a mag mount antenna on my car. But I have heard that they really don't work. Someone said that because of the magnet their isn't any capacitive coupling for the RF ground. Is that true? So a mag mount would work just as well if I set it on my picnic table? Also, does the coax attached to it as a ground? If I change the length of the coax, will a mag mount quit working?

Thanks.

I enjoy reading this group, mostly for short sweet questions with short sweet answers. I take the time to sort through all of the questions and all of the responses in a thread because if I can't offer some advice, then maybe I'll learn something. In this case, I feel my time is wasted by both of you because there's nothing I can offer to this purely emotional exchange, and nothing I can learn from what's being offered. I think the majority of the readers probably feel the same.

Can you guys take this to a more private venue please??

Yea, I guess that the way it goes. I always get that part mixed up. It's
been a while since I built one so I'll have to go back over my notes.
I have previously built a trap dipole for 10, 15, 20, and 40 Meters and
a vertical for 10, 15, and 20 Meters. They both worked great, but I just
don't remember the exact order of things. That's what happens when you
get old I guess. :-)

Yea, I mention that further down the post, but you clipped it off.

??? Wouldn't that just make it usable on 10 Meters only? I thought he
wanted to use it on 6 and 10 Meters. Maybe I read something wrong.

I'll have to look up the article that Ian references. He seems to have
a better idea of what Matt is looking for.

p.s. Every time I post some spambot out there tries to send me some junk
mail. I don't have any real problem with that because they all get
filtered out, however, with this last post they tries to send me a
email with a virus in it. It doesn't cause me a problem because
all my email is scanned and the virus was removed before it ever
got to me. But be aware that it is out there.

Just because s-params are in mag <ang format and not in a + jb . At
least I've never seen tham that way. Furthermore, I know exactly
what PB is referring to, in case you didn't notice the page number
refs.

Yeah. I'm on hold here, so I haven't left yet. Delays.

>That's the pot calling the kettle black. Aside from the need for
>others to repeatedly spell things out for you, you're also the guy
>who braged about the record setting flame war you had with some
>dude. I don't suppose yuo consider that a waste of bandwidth. Don't
>add hypocrisy to your transgressionsl.

You know nothing whatsoever of the nature of that thread and my input
to it. On that particular forum, my input was instrumental in
assisting an innocent person to defend his hard-won real-world
reputation against malicious allegations made over the Internet. It
cost the transgressor half a million pounds in damages, thanks in no
small part to my guidance and support in an area of expertise in which
I *do* unquestionably excell. I'm not here to dish out advice, I'm
here to try to learn something about a subject I'm not fully
conversant with.

>> by just simply stating "no it's not possible to perform a summary
>> translation between S and Y parameters by mappings on the Smith Chart"
>
>But for the third time, it is.

For at least the *fourth* time, it isn't!

>The eqs are for getting a *numerical*
>answer. If you have the chart, you just read the conversion off of
>it directly. Start with the example on pg 105.

Nope. The example on p.105 is nothing to do with converting between S
and Y parameters; it simply demonstrates a graphical method for
expressing a normalised load impedance in the form x +/-jy as a
reflection coefficient in terms of a magnitude and angle; that's all.

And as John W said, how do you tell whether the point referred to on the Chart is actually a Y-parameter at all??

>That's three (or so) times I've told you and yet you can't
>understand why people tire of your lack of understanding.

Some people have a gift for expressing themselves lucidly. Roy's single, concise posting was an example of that craft. You have demonstrated nothing of that calibre.

>> and we could all have got on with our lives.
>
>Didn't know you had one ;) ... couldn't resist.

I do, but it's x years minus 1 day thanks to your obfuscation.

>Ok. You're right. I added nothing. It was all bs. You *can't* do it
>on the SC and you *must* use the conversion formulas. Happy now?
>Bowick and I are both wrong.

I didn't say Bowick was wrong. I never said that Bowick stated it was possible to make the conversion solely by means of the graph. You, OTOH, still say that.

Hi Bob,

Many claims are made for mag-mounts that just don't stand the test of common sense. The capacitive coupling is one of them. Too often this claim is taken on faith.

This is not to say all models are faith based however.

Testing will undoubtedly reveal that the mag-mount will match to the transmitter, but again, this says nothing of the performance of communication.

The faith based arguments have the mount base being the plate of the capacitor meeting the plate of the chassis. I have yet to hear this analysis being examined by peeling away all the extraneous layers to reveal this plate.

The faith based arguers throw up their hands and insist "it must be there! otherwise the antenna wouldn't work!"

Such arguments are then dashed against the rocks when past mag mount users offer reports that when they replaced them with true metallic connected antennas, those antennas outperform the mag mounts.

Aside from the conflicting evidence of probable poorer efficiency, the necessary capacitive coupling from this presumed plate then requires that it have leads, which must in turn lead back through the path of chassis metal to reach up the cable to the opposite plate. Faith based arguments quickly collapse when pressed to this consideration.

Another failure of the faith based argument of the plate in the mount is found through its redundancy to already existing capacitance in the cable leading up to the mag mount. A six foot coaxial cable feeding the mag mount, when tightly, mechanically coupled to the chassis through simple routing paths to the mount, also are tightly,

capacitively coupled and would exhibit just as much, if not more capacitance than could be attributed to the plate presumed to be in the mount.

Setting the mag mount on a picnic table would seem to be an exercise in failure. The common away-from-car advise is to mount it atop a cookie sheet. Testing is advised in other words, and this includes testing against a true, metallic connected antenna. However, if you had that opportunity, you would do well to simply mount the metallic connected antenna and enjoy talking on the radio. To answer your other question about changing the length and performance going to hell. This characteristic in itself suggests you be on top of the required lengths and combination of such influences, or toss that air cooled resistor.

1065. Re: Update on DLM Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-07-31 19:28:51 UTC
From: Rick Karlquist N6RK <richard@karlquist.removethis.com>
Message-ID: <TpSOc.64250$eM2.35002@attbi_s51>
Source record: 91686

Here is a telling quote from the URL cited:

QUOTE:
Recently a 9-inch DLM operating in the 150 MHz marine and business band out performed an Antenna Specialist 5/8-wave antenna with a total height of 54 inches. Besides matching the radiating level of the AS 5/8 wave antenna it also exceeded the AS antenna bandwidth by 1 MHz. The test was conducted on a 4-foot square ground planes system, which emulated a typical installation. (Vehicle roof top etc.) To verify that the test were conducted on a level playing field the 5/8 wave antenna was measured against a quarter-wave vertical radiator matched for a 1:1 swr and it did exhibit 3 dB gain over the quarter wave antenna. The DLM was then mounted on the same ground plane system and nothing was changed.
UNQUOTE

So what he seems to be saying is that his antenna outperformed a 5/8 wave antenna which in turn outperformed a 1/4 wave vertical by 3 dB. Thus, he has in essence claimed 3 dB gain over a 1/4 wave vertical. There is simply NO WAY this can be correct, unless the small ground plane just accidentally helped one antenna and hurt the other. Or maybe THE FEEDLINE WAS RADIATING.
Hmm, where have I run into that before? The CFA maybe.

The Smith Chart has served its purpose.

It was a much-simplified version of earlier, more complicated charts, dating back to the Victorian age used to solve electrical engineering problems involving complex hyperbolic functions.

It applied ONLY to the HF spectrum, serious calculating errors occurr if applied to the LF spectrum and below although few engineers realised this. And still don't.

But it became popular with design engineers immediately following its introduction in the late 1930's when HF broadcasting, TV and Radar, and relatively short, low-loss HF transmission lines became the vogue.

The design and use of HF and VHF lines was much further accelerated during WW2 when all the principal participating nations indulged in vitally-urgent, secret work associated with VHF communications and Radar. The Smith Chart became available just at the right time. It could almost be considered as a war weapon used by all sides.

But it became reduntant just as rapidly on the invention of the scientific pocket calculator. In particular calculators which had hyperbolic functions. The pocket calculator could now, much more easily, with equal facility, undertake transmission line calculations involving the whole of the frequency spectrum from DC upwards.

It is said that, these days, the Smith Chart has eductional value. It allows problems to be visualised. Indeed it does. But there are other just as good educational methods which involve mathematical procedures.

My first association with transmission lines was in 1944/5. I have never used a Smith chart in the whole of my career. Neither have I ever met anyone who has. Perhaps I haven't met many people.

The Smith Chart, as sentimental and as nostalgic as it may be, is redundant.

Source record: 91688

I have planned to build a slim jim antenna for the marine VHF (about 160 MHz) band and to put it into a weather resistant pvc tube.
In fact I need another one for 422 MHz band. Both will be used for reception purposes only.

My question is: is it posible to combine these two antennas in just one tube, so that they don't disturb each other??? The antenna design is conform described at
http://www.ha.cz/a_spionaz/urobsisam/radio/doc/tech.htm#Siting

If not, what is the minimum (horizontal/vertical) distance needed between the two slim jim tubes in the mast?
And also, what is the best method to mount the slim jim tube to the mast?

Thanks in advance!

Luc

Yep, most of them work fine.
I took one apart once at the mag-mount
The one I took apart had a thin plate between the magnet and the car which
was soldered to the braid.
The capacitive coupling worked fine for 2meters and 10 meters.
I haven't tried a mag-mount for lower freqs - so I can't address those.

Like the design. and it looks good too.

I tried a similar setup trying to space the elements 1/2-wave apart.
I Couldn't get it quite right because 1/2-wave in air was farther apart than 1/2-wave coax between the elements - because of the velocity factor of the coax.
(i guess I could have made the stubs between elements 1-1/2 wavelengths, but the simplicity of the design would have been lost.)
How far apart was the spacing of your elements in your colinear ?

Well, Reg, with all the modern methods of calculation now available, the Smith
Chart may have outgrown its primary usefulness for this Century, However, I
take pride in having used it as the then only method of obtaining quick

solutions to antenna-transmission line matching problems that I faced when developing the antenna systems for the World's first weather satellite, TIROS 1 in the late 1950's. There also were no hand calculators then--I had only my K&E log log decitrig slide rule. What's more, I had no fancy digital machinery for measuring impedances at VHF and UHF like those available today. I was limited to making hundreds of measurements with only a slotted line and a SWR indicator. Yes, Reg, the SWR and the distance from the load to the minimum voltage point on the line was the only procedure available then for making complex impedance measurements. Don't ever think that SWR is unimportant, as you have asserted many times. In my case then it was vital to obtaining the measurements. The Smith Chart was then the only means for transferring the SWR and null distance into useable impedance data.

In addition, if a problem arises for which there is no calculator program immediately available, the good ole' Smith Chart provides a quick solution. When I'm at my problem-solving location my hand calculators are within arm's reach, but my Smith Chart is never more than five feet away. Are you aware of the JIC principle? I call it 'just in case'. My Smith Chart is my JIC. You may call it my security blanket if you like.

Could you please explain that a bit more? The chart is a graphical way
of doing mathematics. Where does frequency enter the picture?

If you mean that the characteristic impedances of 'transmission lines'
at low frequencies aren't resistive, I quite agree.

Most people agree that they work but are usually at odds over
how well they work. One can only give a personal account of their
use.

During the last sunspot cycle, I ran a Radio Shack HTX-100 on 10
Meters. I used a mag-mount, also from Radio Shack, that was only
3 Ft high and was base loaded. It had about 10 ft of RG-58 on it
and was very easy to adjust. The antenna was stuck to the "air foil"
on the back of the trunk lid on a 1989 Firebird.

While driving the roads of Phoenix Arizona, I was always able to
hit the mid-west and occasionally the east coast. All of the
contacts were solid copy and I did it on the 5 watts and 35 watts.

So I would say that they work.

Major employers, especially those with government contracts, require
pre-employment drug testing these days. Maybe that's why few engineers
think Smith charts somehow become invalid below a certain frequency.
Your mileage, obviously, has varied. :-P

Perhaps Reg can also tell us in which year since the Chart's inception
the mathematical relationship between a graphical solution to a
computation and a numerical one broke down?

Hard to say from the pix but a good gin pole will have the rope ran up the
bottom of the pipe and over a pully at the top. If the pole breaks or bends
the tower section will still be supported by the rope and will not fall to
the ground.

There was a pulley on top and bottom too.
The cable came from the winch located 1m above the base of the antenna, went
through a pulley located also at the base of the tower (close to ground
level), went up to the jin pole's pulley and went again down directly to the
ground were someone kept the cable tight.

I added 3 more pictures on the refered page

Well your web page link is about pirate radio operations (R. J. Kojetin
listed as of 2000),
and this antenna design can found on a number of different web page.
http://www.ha.cz/a_spionaz/urobsisam/radio/doc/omni-ant.htm

The "Slim Jim" is an aerial (antenna) designed by G.C. Judd G2BCX and
featured in the "Two-meter Antenna handbook"
This book was published by Newnes Technical Book (ISBN 0 408 00402 9)
http://www.johncath.force9.co.uk/omni%202mtr.htm

http://www.qsl.net/qrp/ant/slimjim.htm

In many ways, this design is a modified "J-pole" antenna design -
which is a very popular and inexpensive antenna to build.
http://www.dxzone.com/cgi-bin/dir/jump2.cgi?ID=3481

http://www.hamuniverse.com/jpole.html

Dual band designs do exist - marine (160 MHz) and UHF

> I'm thinking about putting a mag mount antenna on my car. But I
> have heard that they really don't work.

They do work. But that all depends on ones definition of "works". The antennas do radiate RF. The really short stubby ones tend to be rather narrow banded meaning the
SWR is near 1 to 1 at the center at channel 19 or 20. Towards channel 1 or 40 the SWR gets progressively worse and can rise to 2 to 1 or 3 to 1. The exact value depends on the model of antenna you buy and how it is installed. If you're lucky the antenna may come with a chart showing the SWR verses frequency. I've seen these on the ones at Radio Shack for example. Basically as long as the SWR remains below 2 to 1 the radio shouldn't have a problem.

The other factor is really short, like the base loaded mag mount, antennas are not very efficient. A lot of your transmitter power is wasted in the loading coil. In your case if all you want is short range communications, a few miles, then this may not even affect you much.

> Someone said that because of
> the magnet their isn't any capacitive coupling for the RF ground. Is
> that true?

There is capacitive coupling for the RF ground, so don't worry about it.

> So a mag mount would work just as well if I set it on my
> picnic table?

It might IF the table is metal, and depending on size too. Wood ones don't, so don't waste your time trying it.

> Also, does the coax attached to it as a ground?

In a perfect world the answer is the coax braid "should" be at ground potenial for RF. The coax itself is not a ground connection. To explaine this would take several paragraphs to get in to the details.

> If I change the length of the coax, will a mag mount quit working?

No. But your SWR meter may show changes, and if the radio has a built-in SWR monitoring circuit it could cause the radio to fold back power output or shut down. What is happening if you see this is the coax has RF current on it on the outside surface and ends up acting like part of the radating section of the antenna.

>insulation.

Hi Roy, I am sure you are correct, I was in a hurry when I posted. I was looking at fig. 20 (b) on page 24-16 in the Antenna Book. It looks like insulated wire in that figure, very confusing as I look at it now. That was what is was going on, the formula below that figure. Upon reading the text, I see the formula is for d of uninsulated wire. Sorry, and thanks for correcting me.

Message-ID: <410c3180$1@news.vo.lu>
Source record: 91707

Hi,

About the rope or the steel cable running through the gin-pole and pulleys, to confirm or change our installation if necessary, I am looking for any URL or free-hand drawings (scanned) showing the all circuit of the rope and how the fix the pulleys on both the segment to lift and on the tower top, even when the segment in higher than the tower.

NB. We have not installed an additional tower to lift the segments. We use the main tower to lift them, taking advantage of an electrical winch to lift the gin-pole fixed on a mobile basket (cage or lift) on which will be attached the mast and the beam. This cage goes up and down, avoiding to climb on the tower to maintain and check the antenna.

Up to now our installation was able to lift 3 segments up to 8m high, so it seems to work (almost) correctly. But a confirmation is always welcome to secure our system.

If you want to send me closeup images or drawing, do contact me either by this forum or via http://www.astrosurf.com/lombry/post.htm to get my private email.

Thanks in advance

The last segment 'd be erected near 5-8 august.

1087. Capacitor loaded vertical question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-01 00:05:17 UTC
From: Jon <jon@portlandbill.co.uk>
Message-ID: <cehc3u$do8$1@news6.svr.pol.co.uk>
Source record: 91708

At present I am designing a 40m centre loaded vertical from an old fibreglass cb antenna about 18' long. I plan to use a single counterpoise of the same dimensions and loaded at the same point and sloping down from the antenna, a loaded vertical dipole if you like. Nothing new here I hear you say but I am planning to add two motor driven variable capacitors to the feedpoint, one in the vertical and one in the counterpoise to resonate the antenna on the bands between 40 and 10m. I can't find anything in my books or on the net relating to shrotening antennas using capacitors. I have used this technique before sucessfully in a vertical for 20-10m with tuned radials for QRP.

I wonder if anyone would like to have a think about it and maybe suggest a good starting point as to capacitor value for use with 100W. I have tried and failed to use antenna modelling software before so this is not an option for me.

Thanks in advance.

Jon G2FHF

1088. Re: trap / loading advice needed.

Source record: 91709

Matt

Take a look at Reg G4FGQ's site here http://www.btinternet.com/~g4fgq.regp/index.html#S102 He has loads of simple software for free use on there, one of which is called coaxtrap. Download the software and use it to work out the dimensions of a coaxial cable trap for 50MHz. I did a test using the dimensions of a fibreglass cb whip that I have here and came up with 7.6 turns on a 10mm former. 10mm is the diameter of my whip here. Take a look in the ARRL antenna book to see how to make coaxial traps. You may also find this site useful http://www.cqham.ru/coaxtrap.htm. I don't think that you will have enough room at the top of the antenna for 10m as the tral will take up a large chunk of that so it might be worth either coiling the 6m antenna wire around the whip to bring the end of the antenna down the whip or adding a capacity hat to the top of the whip. The latter might not be feasable if you are using the antenna mobile. You might also fing the software "vertload" and "helical3" on Reg's website of use.

If you have any problems of need the above explaining please email me. If you send me your cb whip dimensions I would be happy to do the math for you.

Sure they work, but don't expect performance to be on par with the
same antenna on a permanent mount. And it probably won't work very
well from the picnic table for various reasons. But if you do use a
mag-mount, use the same length of coax that came with the mount, or
whatever length is recommended by the manufacturer.

As for those who think a mag-mount works because of capacitive
coupling to the mounting surface, I would suggest you actually try to
measure this capacitance -- you will find that it's not nearly enough
to make an effective counterpoise connection unless your frequencies
are considerably higher than 27 MHz.

The SStran transmitter is a damn good unit,
and will give you up to a mile range
if you're up to building the antenna suggested at their website.

www.sstran.com

The SStran is the most bang for the buck,but if you
want to go cheap, the Vectronics kit is less money, but isn't in the same
league as the SStran unit. There are commercial part 15 transmitters and
antenna systems on the market, but expect to pay upwards of 800 to 1000
dollars for one.

Bob,
Unless you are using a 1/4 wave VHF antenna, make sure it has a strong
magnet, or magnets. I had a 5/8 wave 2m antenna on a name brand mag mount
blow off the roof.

All graphs are redundant and can be replaced by equations or tables.
However, a picture (graph) is still worth a thousand words (or numbers).
A glance at a graph tells me more than an hour of studying endless rows
and columns of numbers.

It has never broken down. It's the engineers' educational system which has broken down. Mathematics gradually became a neglected subject. And that began around 1945. Students and professors were war casualties. Present products of the system are mentally handicapped. They are reduced to using look-up tables and manufacturers' digital-chip catalogues with little understanding of what's really going on in the world.

It suffices after a fashion but is very poor engineering economics and a squandering of the Earth's limited resources.

Which is a long way from S-Parameters.

Reg.

1105. Modling a coil

I ended up with a antenna, from a trade, that is a fiberglass stick
tuned around 165 mhz.
I found the instructions on the repeterbuilders web site for retuning
a station master antenna. I tried there procedure and could not get it
to work.
I removed the two screws from the base of the antenna and pulled the
element out of the tube what I found was 5 coils with spacers and a j
pole type of base. I want to model this thing using eznec demo but I
don't know how to input the coils.

The end result I'm trying for is an antenna on 2 /440.

Thanks

This question shows a limited understanding of the LF, and below, frequency spectrum. There are an infinite number of octaves.

What is the cut-off frequency of a simple R+C high-pass filter?

It is first necessary to specify how many decibels the response must have fallen.

C'mon Reg, answer the question. What is there about a Smith chart that
makes it incorrect at low frequencies?

John

Reg

I think you are wrong about Smith Charts being limited to use at low
frequencies. Maybe you can take time to tell me where my thinking has gone
wrong. I'm not really a good engineer. I avoided the mathematical aspects
of design whenever possible.
I considered the Smith Chart a plot of *all* impedances with + R values.
That means that there is a point on the Chart that represents every
impedance independent of the frequency associated with that impedance
determination.

I have maybe been in error when I state that I can look at an impedance
plotted on the Smith Chart and identify which combination of the minimum
number of reactors will be best for matching that impedance to the
impedance of your choice, at any frequency. I realize that there are
conditions where my method gets difficult, but, I contend that a Smith Chart
is a nifty tool for those of us who arent smart enough to do the math.

Jerry

Time delays seems to infer the involvement of some capacitance into the mix
between 2 points of earth ground.

the time delays infer a breakdown in insulation when the voltage builds
sufficiently up to the insulation breakdown point.

So find the breakdown voltage of the insulation and the capacitance and the
applied voltage and the resistance, and you may be able to predict a time
delay.

- I may be wrong - but that's my 2-cents

Damn Reg. So far, I'm really liking what you're writing, history
included. As much as I like shortcuts, they never satisfy my desire
to truly understand an engineering concept which can only be related
(IME and to my satisfaction, etc) via mathematical analysis. If you
tell me that a range of resistor values will light up an LED
supplied with a certain range of voltage, I'm not going to sleep
easily until I know why. Yeah, there are some neat analogies, but
that doesn't yield an ohmic value. Math will.

That's why I'm ranting. Running to Wendy's might be a quick fix, but
it isn't my way and neither is randomly shoving values into Spice as
great of a tool as it is. It's just a tool and it's no better than
the operator.

I should stop now because PB already told me to keep my views to myself if they don't answer the question. I should be plonked post haste.

There are other considerations in detemining how to arrange the
matching net. Once you have the topology, the chart is pretty
convenient, IMO. And it doesn't save you from any *complicated*
math. Obviously, going from j5 to j0 is simple arithemtic - you need
-j5 reactance or suseptance depending on whether your selected
topology calls for a series or shunt.

The nice thing IMO is that you can keep track of each step on a
graph of the transformation and not have to look at a blur of
calculations.

IMO, it avoids no arithmetic at all. You still have to add and
subtract. And with or without it, you have to convert the reactances
to puFFs and Henries for that freq.

I have convinced myself that the Smith Chart alows it to be determned if
it is preferable to add series (+ or - X), or Shunt (+ or - X) depending
where the complex Z plots on the Chart.
I really admire the guys who can match impedances with math only. I just
dont have good study habits, so I'm not smart.

Ok. I think I understand your confusion, now, and I hope I didn't
call it a Y param (part of the OP subject) and just said it's not an
s-param, which as I said, isn't expressed as a complex number, IME.

The example is given as a load of Z = 100 + j75 which normalized to
50 Ohms is 2 + j1.5 and as I've tirelessly tried to drive home can
clearly be read off the chart as 0.54 <29.7 deg

Due to the geometry of the SC, a normal polar/rect (v.v.) conversion
doesn't work and as I mentioned earlier, those conversion formulas
look very much like something that came from the circle equation. If
you have a conversion chart handy, look at the (1-y), (1+y) factors
and consider the fact that the origin is at 1,1. It's obvious to me
that the formulas were derived analytically from

(x-h)^2 + (y-k)^2 = r^2

with h, k = (1,1), i.e., the center of the s-param circle is at the intersection of the unit R and X circles.

Interesting that the +/- signs in the conversion are kin to the hyperbola (no?), which IIRC Reg mentioned (xmission line eqs), but I'll wager it all came from the SC's circular geometry, mainly because I coded an SC chart and went as far as calculating the intersection points where the arc change line width and eventually terminate like a real printed SC, not the typical CAD couple of lines that go to oo . You could say that I have deep carnal knowledge of the chart's construction. My app displays the Z, Y, S params of the cursor position in the status bar and damned if I remember whether I naively (or brainfartedly) used polar/rect conversions for that.

> measure this capacitance -- you will find that it's not nearly enough
> to make an effective counterpoise connection unless your frequencies
> are considerably higher than 27 MHz.

Not really. Consider a magnetic base of 2 inches in diameter sitting on a
painted metal
surface with 0.010 inches of paint. Then as an approximation I looked up
the dielectric constant for epoxy, 3.62, to use for the paint.

Cpf = 0.225 * Er * A / T

Where Cpf is the capacitance in pf
Er is the dielectric constant
A is area of one plate of the capacitor
T is the distance between the two plates

All dimension in inches.

The above example works out to C = 255.88pf

The reactance of 256pf at 27MHz is 23.03 ohms. If the paint dielectric is
higher, paint thinner, or the antenna base larger in diameter, then the
reactance would be even lower. Remember this is reactive, not resistance. By
adjusting the antenna a bit you can compensate for this.

Vector network analyzer. Since the mid-1970s, maybe earlier, they've
been able to generate both scalar and polar plots of S-parameters
directly. Very handy for antenna work, if you don't mind dragging 75
pounds of gear around! I just wrote some code to grab Smith-chart plots
off a friend's Advantest R3762AH, and I'm going through some real
hardware envy right now.

> I have to agree there are certain aspects, a few octaves of my education,

True; this thread has been generating more heat than light since it
began. I've stayed out of it since I'm not a certified guru at this
stuff. I don't want to post any incorrect or incomplete information
that will further confuse our esteemed interlocutor. It'd probably be a
good idea for all others who aren't fully up to date on the principles
to do the same. :)

Conversely, I've already hit 'print' twice on J. Woodgate's posts to
keep them around for posterity....

Source record: 91642

Hi Walt,

Believe me, I DO understand and sympathise with your genuine feelings about the sentiment and nostalgia associated with the Smith Chart with which I have no criticism. It was a highly valuable, fast, sufficiently accurate and much-esteemed tool when nothing else was available except tedious tables and the slide rule.

The reason I never found a use for Mr Smith's chart was an obvious one - I was involved with research in the spectrum from 1/20th of a cycle per second up to several MHz at which frequencies the chart, of which I was not unaware, was useless. Line lengths extended up to 3000 miles and, yes, there were standing waves albeit rather damped.

So my education on transmission lines was self-taught and thorough. It is not surprising I arrived at a different set of viewpoints on line behaviour from that acquired by the majority of engineers, at that time, who had worked their simplified way downwards from the newly invented magnetron at 3 GHz. (Indeed it is from where I initially began myself.)

My present criticism is not so much of SWR meters as of the people who imagine they are using them. The only people I meet are on newsgroups such as this who are a mixture of professionals and amateurs, very often both. It's very difficult to distinguish one from the other. As you may have noticed I have classified many of them, without being specific, yet kindly and humorously I hope, as being old wives who tell tales.

They tell tales, not only because they plagiarise each other, but because they have mis-educated themselves, without ever thinking about it, by taking the name "SWR Meter" literally. Whereas the so-called meter itself does nothing of the kind. There is not even a line which exists on which the SWR is measured. Consequently what is really going on is misunderstood. Virtual short and open circuits, reflected power, etc., in the way of explanations are just so much nonsense. Conjugate matches in practice do not exist. They are just interesting talking and arguing points.

All that's necessary at HF is to change the name of the SWR meter to TLI (Transmitter Loading Indicator) and start reasoning from there. Life is really quite obvious and simple, easily understood by novices welcome to this fascinating hobby of ours.

I see through the kitchen (combined computer room) window that dawn has broken. The bottle of Premieres Cotes de Bordeaux is 3 parts empty. And so to bed.

Yours, Reg, G4FGQ

>Reaactance depends on it. I must not understand your question.

Reg wrote that the Smith Chart doesn't work at low frequencies. Since
it's just a way of solving equations, it can't fail to work. What
'fails' is that at low frequencies, either different equations apply
(no) or different terms in the equations become significant (yes).
>>>
>>> If you mean that the characteristic impedances of 'transmission lines'
>>> at low frequencies aren't resistive, I quite agree.
>>> --
>> ================================
>>
>> The characteristic impedances of ALL practical lines aren't resistive.

Well, yes, but at high enough frequencies, the reactive term is small.

Zo^2 = (R + jwL)/(G + jwC)

For high enough w (omega), provided R (series resistance) and G (shunt
loss resistance) are low, Zo^2 = L/C.

> But
>> your statement just about sums up the situation.

You agree with my explanation above, that it's not the chart that
'fails', but that terms in the equations change significance at low
frequencies?

when you really need an LP pi for harmonic suppression? Please
elaborate. Sounds like an excellent contribution waiting to happen
to those who are teachable.

> I really admire the guys who can match impedances with math only. I just
> dont have good study habits, so I'm not smart.

Eh? It's not math. It's arithemetic. Give yourself more credit.

Match 50 + j25 to 50 + j0 .... ok you need -j25 which is a series
cap that suppressed no harmonics or a practical shunt inductor that
does. Assume I'm assuming the application I'm assuming ;)

How do you infer the correct topology from the chart only?

MMike

I havent learned to type either.

I wrote a short article in Electronic Design magazine in 1966 wherin I outlined a simple way of predicting which combinations of series and shunt reactances would be most appropriate for matching any given impedance. I'd have to re-read it to learn what I wrote. I sure couldnt give any advice about using a Smith Chart from "the top of my head". I've been away from engineering since 1969 when I was layed off from TRW.
The basic thought elaborated on in the article was -- divide the Chart into 8 sections, chosen to identify what combination of reactances are most suited for producing a match. I think that anyone who worked for a short time with impedance matching would find the article unnecessary.
The article included some information on how a Z theta chart can be usefull in analyzing how transmission line transformers effect impedances.
I have forgotten everything I ever knew about Z theta Charts.

==========

Depending on our particular educational history, we all have our separate preferred ways of studying technical situations. And we all usually come to the same correct conclusions.

I too become exhausted by studying endless rows and columns of mere numbers.

Graphs are indeed very useful. But I often find that the form of a mathematical equation provides just as deep an insight into what is really going on in the practical world. Praps I am fortunate at being equally adept at both analytical forms. It must have begun during my school days.

The advantage of equations over graphs is that they are nearer to the quantitative than they are to the qualitative world. They are more precise. And in engineering it is numbers which, ultimately, matter most.

You can't. But then the chart doesn't act as a typewriter or Turkish
bath, either. The chart will give you both T and pi solutions. You make
the choice between them on other grounds, such as harmonic suppression.

Pretty easy...The hardest part is finding a suitable variable capacitor...And thats not hard really...You can order them on the web. I've been making some simple PVC loops. I have a 16 inch circle loop wound on a humidifier blower housing, and I have a bigger diamond loop made from PVC. It's very simple. A 2 inch PVC mast, and 1 inch "actually 3/4" PVC crossarm that is fitted through drilled holes in the larger PVC mast. It's 6 ft tall counting the mount, 5 ft across, and is 44 inches per side. "5 turns". I have switched multi-gang variable caps, and also some fixed value caps for LW, and can tune from about 200 kc to about 2.4 mhz, if I remember right. That thing will blow the doors off any real small loop. But my 16 inch loop works well also. The s/n ratio is better on the large loops, but if the radio is sensitive, even a small one will do ok.
I have one simple PVC design on my web site. I made one of those for a guy on the shortwave NG, and he seemed to like it. Was all the standard 3/4 inch PVC, and T's, etc...With that wood mount I made for his, it rotates, and can also tilt. It clamps to his table. All the parts are at any home depot, Lowes, etc.. Well, except the capacitor...I scrounge some from old analog 70's, 80's stereo receivers.
They have multi gang caps that are great for MW loops. BTW, my usual radio for MW is my IC-706mk2g. Nothing fancy, but it is a great MW radio for casual use. Has a pretty wide stock bandwidth, and the audio is fairly decent. Much better than some ham receivers with tight stock 4.8 kc filters for AM. I get plenty of signal from either loop for the 706. No preamps needed. My loops are both on the floor on heavy stands, and can rotate. Nothing beats a good large loop for daytime MW...:) I regularly listen to San Antonio, Austin, etc, just like I'm a local.."I'm in Houston". Also works great at night, but the nulls are not as deep as in the day. Still better than a longwire though for busy freq's. MK

SIMPLE PVC LOOP DESIGN

Hi,

I think that we know that my friend. This is not our first tower and we all already have do similar installations, and I even wrote a short article about it as well http://www.astrosurf.com/lombry/qsl-rotator-tower.htm p2-5. However I am personally less familiarized with such a job than my friends. But on the contrary I was more security oriented that most of them. But as there was only one director on the field, I could always go against his decision or we have no more time to buy the additional material. All people were in site and we had to erect the tower now, not tomorrow...
That said in practice we could do the job without problem, even if not everybody had an helmet or gloves for example and didn't think that some pulley 'd break.

3 people climbed on the tower : 2 most of the time and a third to check some detail. There was also only with people directing the work.
One of us was specialist in aluminium work (on plane, etc), another one was expert in scaffolding before he retired and a third used to work on sloping roof and on high chimneys. We have not really high iron workers.

For the gin-pole the guy who built it in assembling 2-3 tubes recognized immediately that his system was faulty. But is worked up to over 10m high without problem as long as the all system was well check and secure with ropes (4mm steel cable, the one use by the eletrical winch).

Of course I think that in erecting any tower we learn something new each time.

This time, 2 rollers attached to the lift system (a new one) made of steel broke !, we lost two other pulleys because they were made of teflon. They were replaced with steel ones. Hopefully we had full of spare parts up to mini-clamps because we already learnt lessons from previous similar experiences. Even the winch (a new one) didn't wind correctly and we had to unwind it completely and wind it up without making knots. This steel cable 4mm think will be replaced by a new 50m roll.

But the simpler the best : another time to another friend who desired to erect a 14m high cranking tower (from the same manufacturer) 60 cm wide (8 years ago now) we simply assembled all the tower horizontally at ground level, then pulling on ropes to erect it progressively vertically. This method was faster and much simpler. We were 18 people, 15 at ground pulling, 2 other holding the tower and a third in a tree with a "tire-fort" (sort of manual winch, cannot translate). This solution worked perfectly without error or broken part. Good to know.

Why Jack, did you never do a mistake in your life... ?

We are not ironworkers but simply radio amateurs expert in various other fields. However, many are used to work with electronic parts, steel bar or aluminium or have discussed a lot with specialists or people having already do similar works.
Ou group has erected a lot of antennas in our area (they are several major ham radio club around here and thus many amateurs who have the place to erect a beam) to know what are risks and how to proceed.

Unfortunately each time, the tower is different (bigger, smaller, with a lift, placed on a roof, cranking or not, etc) and sometimes the owner hasn't think about all detail or did'nt buy all required part because they were not available in the shop when he did his purchases.
We often discover that only once on site, even if we speak longtimes before, often during meeting at radio clubs or even by echolink or visiting the installation of other amateurs using similar tower.
In this last experience, the owner visited 8 times a friend having erected a similar tower to be sure of all detail (mainly how worked the winch to lift the cage and how he fixed his heavy duty rotator on top on the cage to avoid that the beam element touch the tower.

Many people think that they are able to do any kind of job without looking for information. This is far to be true because most of the time, as amateurs, we often imagine complex solutions instead of the simpler ones. Many of them refuse or rather don't think about the security issues (of people and material) and buy often undersized tubing or accessories.
This is here that problem began, reason for which some of us have a spacial suitcase full of quality parts and of various sizes, from the mini to the largest. But the chance and hasard (risks) are never far away, like Murphy...

Hopefully the smartest of us and also handymen and have a long experience in their back and have gathered many field experience and know usually was is good and was is faulty or to avoid. They gathered also a lot of tools and their long experience is appreciated.
So all together we usually do an excellent job, at the condition that the owner buy all parts that we listed or suggest him to buy and don't forget any tool and doesn't sacrifiy the quality for a few euros...

Thierry, there are some places and some jobs where if you make a mistake, people, either yourself or others or both, will be killed. Amateur Radio is not defined as one of these occupations, and no amateur has any business working aloft with rigging and equipment unless he was properly trained in that field. That certainly doesn't stop many from doing it, but it doesn't make it safer because they survive it. The skills sets that seem to congregate in radio are amazing for sure, and the field-expediant thinking and can-do attitudes are good for all invoved in the hobby. But there are some things better left to professionals. Anyone who doesn't think a lot of Ironworkers die doing what they do better than anyone else could, is just delusional. The bravado I've witnessed from so called antenna-tower experts far outweighs their knowledge of safety, strength of materials, rigging principles, or safe working aloft. Even the better ones at it are not properly qualified to train others, and so often enlist any brave soul they can find as riggers, connectors, ground support, etc. All the blind leading the blind. I happen to know better than to work with untrained people at the effort of erecting antenna towers. I knew better when I erected steel as a professional and I still know better 20 years later. But as I said, some people's purpose in life is to serve as a warning to others. Don't let one of your friend's falling to his death make your club that purpose. Hire a professional company and take pictures from a safe distance.

>adjusting the antenna a bit you can compensate for this.

Reality has a way of introducing unforseen factors into the equation,
such as the increased distance and air gaps between the plates caused
by the non-scratch surface of the base (which sets the dielectric
constant closer to 1), the paint/primer/wax resistive and dielectric
properties at RF frequencies (which, for many substances, is radically
different than when measured at the frequencies used to determine the
referenced constants), the ESR due to poor RF conductivity of steel (a
ferromagnetic material) when saturated by a magnetic field at the
point of contact, etc, etc. And don't forget that this capacitive
reactance and ESR must be added to the ground impedance of the vehicle
at the point of contact, which, as we all know, isn't exactly ideal.

Regardless, my suggestion was to measure it, not calculate it. It's easy to measure yourself -- just find yourself an old mag-mount antenna, remove the whip and loading coil, lop off all but a couple inches of the coax, strip the coax shield, plonk it right next to a permanent mount and measure the impedance between the shield and ground with an impedance bridge. It's big. Typically it will measure several hundred ohms, which is a pretty crappy ground. If you can, remove the magnet from the mount, measure again and note the difference.

Jack,

I perfectly agree with you and I do it each time that I estime the projet over my skills and know-how, what could be this subject (electricity, problem with my car, building, etc), all the less that I not pretend to be an handyman.

Other times, if the job is not too big, without any risk (not heavy parts, electricity involved, etc) I try to do it, to learn and to experiment by myself. Of course sometimes I do small mistakes like many amateurs probably, but I learn a lot too.

However, we cannot refuse to help friends who prefer do the job themselves with skilled or experimented friends (we erected 8 towers now) than calling for a specialized company, much more expensive. OK the security will be ensured, the job will be well done and this without any risk for the amateurs. This is the advantage of callign an expert. But you also need a lot of money. Of course this is a choice : you hire a expert of buy a new amplifier for the same price, hi !

On my side I erected a light tower 30cm wide 12m high for a 3-ele beam in company with 5 people only pulling on steel cables and using "tire-fort" (kind of manually winch). Easy, it was erected in less than one hour and with risks reduced to the minimum as there was nobody "below" or near the tower when we lift it up pulling on ropes and cables (the advantage of this solution).
The beam was put in place using a simple steel cable (4mm tick) and 2 steel pulleys (top and down). Here also the only risks were that the steel cable or the antenna elements or boom break during the lift... What what the risk ? Quasi none as the lift last less than 5 minutes. T
the beam weight was 12 kg and I do not know any antenna that broke under such condition.

Refute me if needed, but I think that for such a small installation, relatively light, it is not necessary to entrust it to a specialized company, excepting if the owner is old and no more confident in his strenght or if he can count on freidns to help him. But a few young men 30-50 years

old can do the job with ease if all is well prepared, the briefing complete, and the simulation well done before by people having already proceeded to such installation. Of course for a novice this is a job at risk as he will use for the first time maybe a winch or other tools...
Therefore, we are a few people to have a lot experiment and we try to help the novice to avoid mistakes, but as I told you we cannot avoid that the owner buy accessories of poor quality, and the risk is well there I recognize... but we cannot always come with our own gin pole or accessories.

But this time I learnt the lesson as well, and we will build a few more gin poles (in steel) to avoid it breaks next time that someone ask us to erect a pylon by this way. The gin pole used this time was in fact the only tool that 'd have been of the highest quality after the tower sections. Unfortunately it didn't belong to our team...

Now, if I had to do the job for me again installing a larger tower (say 50 cm wide, 12 m high for a 5-ele beam or so) or stacked beam for HF bands for friends, I 'll deny and I will entrust this job to an specialized company to avoid any accident. I am not fool yet. As you told, preserving the life of people if more important than spare some money.
We refused only once such a job and your friend called a small crane for help.

>Well, you almost have it correct. The trap should resonate in the
>middle
>of the band you wish to operate.

Not always. Matt knows exactly what he's looking for - he really does
mean a trap that is resonant *between* the two target bands!

The parallel L/C circuit will appear inductive on the lower band, so it
makes the antenna electrically longer; while on the higher band it
appears capacitive and makes the antenna electrically shorter. The trick
is to work out how to make the whole antenna resonant on both bands
simultaneously.

The original idea was in 'Ham Radio' several years ago:
Designing trap antennas: a new approach by Yardley Beers, W0JF Aug 87
p60

Unfortunately I don't have the reference itself, but maybe someone here
has either the magazine or a CD?

This antenna is much harder to design than a conventional system with
resonant traps, because no individual part of the antenna is resonant on
either band. It needs either a lot of cut-and-try, or a little help from

a computer.

There might have been a BASIC listing in the original article, but I'd
bet that Reg could knock together a program before bedtime :-)

--
73 from Ian G3SEK 'In Practice' columnist for RadCom (RSGB)
http://www.ifwtech.co.uk/g3sek

Exactly so. The problem is not how to make a trap for X Mhz, its knowing HOW to calculate X in the first place. I have done a search of the internet & not found anything that gives the principles behind it. I can find any number of 'tried and true' designs for other bands, but I cannot simply scale them as a) the relative frequencies are different and b) involve symmetrically trapping a dipole wheras this is a Marconi antenna.

I might presume that one would make the capacitive loading on one band equal to the inductive loading on the other. In that case, 'X' would be that frequency at which the ratio of 29 Mhz to 'X' would be the same as 'X' to 52 Mhz?

Thierry, Few people organize their thoughts as well as you do my friend. And so it is likely that any job you participate in is equally well planned. But the point is, you guys are learning this as you go along, and the gin-pole incident is not by any means the only occassion you will have to discover a new principle, strength/weakeness, fault, improper manufacturing or material failure, improper tools, breakage of tools, physical exhaustion of a team member at a critical time, unexpected wind condition, improper response to a command or order at a winch, line, etc. And each time those things happen, your fingers, hands, feet and possibly life will be at risk. In the Ironworkers, we could explain why working at 20, 30 or more stories in the air was really no special feat. It comes with the understanding that all injuries happen between 0-40' (10 meters). After that, you're either dead, or wish death would release you from the disfiguring and crippling pain. So beyond 10 meters, if you fall, it's not going to hurt any worse. You better get used to the fact that you can and will have injuries so bad from a 2-10 meter fall into or around steel that you will never be the same again, if you live. When you fall or are trapped or pinned against steel, cable and machinery, it's not like twisting an ankle on the rugby field. What I know you want to believe but your mates seem unable to take seriously is, you are not riggers! You are old men who have no business up in the air. You belong ON THE AIR, not it it ;-) Paste those pictures of your rigging days upon the club walls and stop your friends from believing they can think these jobs out. They can't. In addition to knowledge of theory, ironworking is alot of brute strength and stamina from doing that every day. When it comes to rescuing someone from a pin or preventing a fall, it's like expecting children or the elderly to be firefighters. They might want to help, but desire is not enough. You get this speech so you can copy it to your mates, as I know you already agree with it.

Best regards,

Jack

In the Summer of 1970 I worked for NASA on the Tektite II project, St Johns,
US Virgin Islands.
I was a behavior observer when I wasn't operating my Swan or diving.
We took data on IBM cards by punching holes with a stylus.
Manually, like they used to vote in Florida.

The cards were then taken by boat to an engineering firm on St Thomas that
could put them in a card reader and transfer the data to magnetic tape.
The tape was then flown to Austin, Texas for analysis. That was slow.

For ham radio I used a dipole. Phone patches back to Texas were consistently
more reliable than the local phones.

Now in my job I plan on remoting data acquisition in remote areas via a satellite internet connection.

My "dial-up" was a TI Silent 700; circa 1977.

I would see if you can get one of the Select-A-Tenna models, or the Terk
AM loop that wires right in to your stereo. Al ot depends on the type
of building you are in, so you might need to position the antenna near a
window.

Try this site, http://www.ccrane.com/am-antennas.aspx for some ideas,
and if there is not a dealer in Australia, try eBay or the like.

Even hiring a professional crew is not a gurentee that nothing will hapen.
I have seen an I beam weighing several hundred pounds fall about 100 feet
when it slipped out of what was holding it on the crane wire. Not too long
ago a man and his son was killed while painting a 800 foot tower and the
wench hung up and tossed them off the tower. They should have known beter
but they did not have all their safety lines hooked up.

Usually when I see someone bitching about Radio Shack it's from one of
the small brained no-lifers who get their kicks from going to Radio Shack
and trying to show off how much more technically intelligent they are than
the clerks behind the counter.

Unfortunately, I can't make an assessment of your web site to see if it's
of the same ilk, because it appears to be shut down.

Awww.....

Let's all say 'Too F...in Bad" in unison. Doesn't seem like you're getting
the
internet support you wanted!

If you don't like Radio Shack, why do you go there? Unless, of course,
you like the abuse you think you get, and go just to get more ammo!

Wait, I didn't come here for abuse, I came for an argument! Arguments
are two doors down on the right.

> Mhz?
>
==========

For ages, I have had at the back of my mind this particular problem.

Input data to a program consists of overall antenna length, the location of the trap along the wire, and the two antenna resonant frequencies.

Required output data are the L and C values of the trap. There's no interest in what the resonant frequency of the trap may be.

Apparently the solution lies in solving a pair of simultaneous equations.

But the situation is aggravated by the fact that there will be no solution for some values of input data because the computer will be asked to find the squareroot of minus one or to attempt some other equally impossible task.

For other values of input data there will be multiple solutions for L and C involving their negative values.

And for many solutions, impractical values of L and C will occur.

The program user would be obliged to go through the same mental contortions as he would when experimenting with hardware in his backyard.

There would be a great amount of work for me to produce a pair of simultaneous equations in a form suitable for computer implementation for a very few number of users. But I'll continue thinking about it.

Thank you for answering my question.
The given solutions offer J-poles rather than Slim-jims, so I think it
will be better to build two tubes, to be mounted separately.

Some of those can be excluded from the start, if you adopt an iterative approach and seed the equations with reasonable values. It might then converge quite readily.

I believe W0JF had solved that problem, or avoided it. Wish I still had a copy of the original article and the program.

>The program user would be obliged to go through the same mental
>contortions as he would when experimenting with hardware in his

There could be significantly more users if they had the tools to design it.

The specific advantage compared with an ordinary trap is that you aren't using the L/C circuit at its resonant frequency where the circulating currents reach their peak, so the I-squared-R losses are claimed to be

significantly lower.

>But I'll continue thinking about it.

Please do, Reg - it looks like just your kind of problem.

Will work just fine! Put it on your car where the is some metal. The
magnet has no, none, zero, impact on the E fielf but the nearby metal does.

Mag mounts are FB.

I'm using an FM25B, range is about 1/2 mile with the supplied
whip antenna. Excellent audio.

Knowing the long lines Reg was associated with, being on the order of 3000 miles, at low frequencies the Smith Chart wasn't going to work when the line attenuation gave the Zo such a high capacitive reactance that the inward spiral of impedance vs line length would be too steep to permit the Chart to be useful. It isn't just the frequency.

Hello Steve:

I fell out of my chair laughing at that one. That is first call Redneck
all the way.

But I must admit I have a bunch of coaxes entering my radio room from a
sliding glass window.

But the all time great was when my ol man (Dear ol Dad) knocked a hole
in the wall with a slege hammer and length of 1 1/2 Pipe. We needed to
get the coaxes in the radio room for the Moonraker 4, and Omni Antennas.
We had rented a house for a short while while getting another house
ready to move into.

The coaxes fit in the hole just fine. A few rags to keep the cool air
and bugs out, and started to hammer the San Fernando Valley from high a
top the heigths of Tujunga.

Oh the memeories.....

Jay in the Mojave

Thanks a million, Reg, for the insightful response. I really appreciate the cordial manner in which you explained your position.

That being said, I must ask whether you have received the many emails I sent to you during the last two years? I never received a reply from any of them. I could only assume you were offended by something I had said earlier.

If you didn't receive them I sent the first when I was in London in June 2003, asking for your phone number so we could arrange to meet. With no response I sent you three more from the cruise ship we were on, one from the North Sea and two from the Baltic, and the fifth when we returned to London. The last one I sent was in May 2004, again trying to detemine if I had offended you, but alas, still no response.

As you can surmise, I'm sending this on the rraa on the chance that my private emails found the wrong address and you didn't receive them, although they were not returned. I hope there is a technical reason why I didn't hear from you, because I really did want to meet you while in England.

Interesting article at
http://www.freerepublic.com/focus/news/1182979/posts?page=22
so much for my 300,000 km/s "constant" :-(

extract:
>>The theory is deceptively simple: The speed of light is not constant, as we've been taught since the early 1930s, but has been steadily slowing since the first instance of time.

If true, virtually all aspects of traditional physics are affected, including the presumed steady state of radioactive decay used to measure geologic time.

It's an intriguing story – and like many revolutions in science, it begins with observations that just don't fit currently accepted scientific dogma. <<

Right, it's a comalong. Thanks for the translation !
The only problem of this method vs. the gin pole is that it requires many
more people to do the job (15+ vs. 3-4), and its is never easy to ask 15-18
people to be free at the same time, even for a 1 hr job, even asking in a
club.

From: Thierry <"to answer direct see http">
Message-ID: <410d525e@news.vo.lu>
Source record: 91591

Hi

One of my friend come home with a fine question.
He is in the process to buy a new beam and found Steppir quite interesting due to its auto adjusting without moving the elements (all tuning per band is made inside the tubes in winding up a copper strap).

Question to Steppir users as I am not sure of the answer:

Is the separation between parasitic elements important as, in all cases, there is an adjustment on each band ?
We ask for the question because we would like to move the central element of a 3-ele steppir multiband beam of about 50 cm to the right /left in order to be able to take the antenna down to the ground (around the pylon). Up to now the central element is in the passage. A way should be to me it slightly to the L or R...

Is it possible or not without changing the performance (mainly SWR) of the Steppir ?

I don't think you can do all bands 40-10m with a fixed inductor center loading, and a variable series capacitor. Most of the shortened center loaded designs I have seen add inductive loading until the antenna looks inductive at the frequency of interest. Then they use a series capacitor to tune to resonance. Even then you may not have a 1:1 50 ohm swr. This means, in order to change bands, you will need to vary your inductor as well as the motor driven capacitors.
There may be a magic value of inductor that will get you close on all bands, using just a variable cap. On 7 mhz and 14 mhz, or 14 mhz and 28 mhz the vastly different input impedances of the antenna seems to rule out using just a single capacitor for matching.

Can you just move the mast to boom clamp 50 cm
instead of relocating the element? Moving the element
50 cm would degrade F/B ratio considerably. You
might be able to reprogram the control box to fix this, but that would
be a lot of work and you would have to know exactly
what you were doing.

Probably what Reg is talking about is that the 1.0 normalized value
in the center of the Smith Chart lies on the purely resistive horizontal
line. Thus Z0 = 1.0 + j0 (normalized). Reg is probably saying that the
Z0 = 1.0 + j0 assumption is not valid at low frequencies for the average
transmission line.

Yes, and that is one of their disadvantages. An engineer can arrive
at a perfect quantitative solution without an iota of understanding
of the real-world qualitative physical processes. I personally am much
more interested in a conceptual understanding of the process than I
am in the accuracy of the abstract numbers which are the solution.
Graphs are a visual aid to conceptual understanding that equations
simply cannot match (even with a MENSA level IQ).

Cecil

I can se a couple problems. Both are mine. First, I should have written
that someone is wrong about Smith Charts being *FROM* use at low
frequencies. Second, there was no value in my posting something that was
already covered by others.
I sure agree with anyone who points out that Smith Charts shouldnt be used
where they arent designed to work. I like smith Charts and thats probably a
result of my poor academic education.

Miles are getting longer and seconds are getting shorter as the universe ages.
Since the speed of light is in, for instance, miles/second, naturally the speed
of light has to change as the universe ages. It's a no-brainer.

Richard Feynman, who had a decent IQ himself, said that he couldn't
approach anything analytically unless he managed to get an intuitive
feel for the thing first.

The good thing about "gut feel", from an engineering standpoint, is
that it's a good sanity check on the equations. My engineers sometimes
present me with an analytical result that just feels wrong to me, and
it usually - but not always - is. Graphs are also wonderful for
feeling how things work, just as analog meters sometimes are so much
more useful than digital ones.

Smith charts can be used to solve purely lumped-element problems, too.

I wonder if Smith charts have ever been used for analyzing 50/60 Hz
power grids. Their losses are fairly low.

I did just for grins and giggles Frank. On my old 1/4 wave 6m mag mount, I used on my old Dodge minivan, I measured 490pf. The base was 4.75 inches in diameter. The base was placed on a steel sheet using 3 sheets of notebook paper. Notebook paper is around 0.003 inches thick, so that gives me the 0.010 inch spacing. Plus this mount also used a thin sheet of rubber over the foil making the spacing a bit higher, thus you would expect the capacitance to be down a bit from the calculated value. So the value I measured is about what I expected. It is important that the foil be intact on the bottom. If missing then the measured value will be much lower.

I suspect that you measured capacitance directly with either a
capacitance bridge or a DMM. Those won't work because they don't use
RF frequencies. I suggested the use of an impedance bridge and
explained the reasons why the frequency was important. As I said
before, if you measure it as I described, the results will be
significantly lower than your measured 490 pF.

Just for the sake of discussion, how does the dielectric constant of
notebook paper compare to that of epoxy paint?

Yes - but way out here in the sticks, who's gonna know?
(answer: nobody) If I lived in a civilized area, it would be
different.

For the serious bootleger, Ramsey also has a couple of amplifier
kits.

Me too. I think that brains are fundamentally analog computers. I mean, when you shoot a rifle or hit a baseball, all sorts of complex adjustments have to be made for the situation, and they're not done numerically. I've acquired sort of this "analog" feel for electronics that gets me pretty close almost without thinking, close enough to be suspicious of calculations that aren't right. I can usually hit a component value or whatever to within 10% just standing up, which impresses/annoys the youngsters who, frankly, are so impressed by my instant numerical results that they accept them without checking... good thing! This analog instinct is a good complement to the math. It saves a lot of time, too, when you just know something will/can't work before you go to the trouble to prove it.

It must be amazing to be a Fermi or a Feynman who have this sort of intuition, but at astronomically higher levels. Fermi would glance at complex differential equations and just scribble the solutions on a blackboard, and his co-workers would spend days confirming his results.

John

Yuri, the only effect on anything I can imagine is "so what"? Radioactive decay is a pretty gross estimation. Likewise if the universe is shrinking, or expanding...so what? The sun is burning out too. The earth is cooling. Maybe these things explain the EH antenna.

Jack

Yuri, did you know there is a drift between radioactive decay and the rings
of the Bristlecone Pine that increases with time passed? IMO, that drift is
the effect of seconds getting shorter as the universe ages. Proof is that I
once could run 100 yards in 12 seconds. Now, since seconds are shorter, it
takes me twice as many seconds to cover 100 yards. :-)

I did.

> Those won't work because they don't use
> RF frequencies.

They work just fine. I use them all the time, on the job and else where.

> I suggested the use of an impedance bridge and
> explained the reasons why the frequency was important.

For checking capacitance in general the answer is no, unless the dielectric shows extreme variations verses frequency and has a high loss tangent. For many materials this variation is rather small, and car paint doesn't dielectric heat much, so the loss tangent is low. About the ESR, equivalent series resistance, which is composed of mainly skin effect on the plates and losses in the dielectric, this appears in series with the capacitance and simply adds to the resistive feed point impedance of the antenna. The feed point impedance of a typical 1/4 wave ground plane with the radials at 90 degrees to the vertical element is around 30 to 40 ohms, so a bit of extra resistance makes the match look better at the expense of a lower over all antenna efficiency. Capacitive coupling to the body of the car is required, if there is no direct connection, to mirror the 1/4 wave element, thus producing the required 1/2 wave element needed for a resonate antenna.

Losses in the car body material are a completely separate issue and has nothing to do with how the coax gets coupled to the car body.

Now if you wanted to measure inductance I would say yes because you have capacitance between turns that effectively reduces the inductance and since the capacitance electricaly apperas in series with it. The same applies to measuring coil Q, and that is because of skin effect and proximity effect.

> As I said
> before, if you measure it as I described, the results will be
> significantly lower than your measured 490 pF.

Measurements are fine, but you also have to know when your equipment is lying. Poor application of test equipment, failure to understand the limitations of the equipment etc can lead one down the preverbal garden path with no warning. I get a kick out of new hires when they ask me why the waveforms they see don't look right on the scope, meter measurements don't look right etc. Then I get to show them all the wonderful ways test gear can screw up and never give you a hint what they're measuring is garbage but yet there is nothing wrong with the instruments they are using. One of my favorites is flipping the leads on a digital meter and watch the reading change 20 percent or more. Most digital meters don't use true differential inputs so the ground side of the meter is at potential and also allows noise in to the meter electronics. The ones that do have much less of a problem like the above. I could go on about what happens to scopes connected to high frequency signals with funny waveforms, high-pots that are not properly ground referenced, hall-effect current sensors etc.

They way to guard against this is to use your head. If the measurement says one thing and a quick calculation, particular if its a simple one, says you should have something significantly different you really need to consider you have a measurement problem of some kind. Nobody would have bothered to produce all the wonderful formulas, equations, and stuff your head with theory if it didn't work. I've seen to many people get hung up wasting time over a bad measurement, and didn't trust their calculations enough to question what they were seeing. It won't be the first time I went to help somebody and ended up taking the scope probe and throwing it in the trash. The look on their face when what they calculated matches the scope with a new functioning probe is priceless.

>transmission line.

Cigar, I think. The imaginary term isn't zero, and in fact is dominant,
at low frequencies, and this applies for ANY transmission line that
doesn't have its inductance artificially increased, because:

Zo^2 = (R + jwL)/(G + jwC)

and at low frequencies jwL and G are negligible.

I had one of those TI terminals; it was a real step up from the ASR-33 TTY. I remember that the TI printhead, on the backside of a little aluminum plate, was real finicky about the paper. If you used TI roll paper, everything was good, since the TI paper was slightly "slippery". But if you put a roll of HP paper in it, the harder surface HP paper would rather quickly grind off the thermal elements of the printhead.

It would then become a very silent 700!

We're looking for a cellular antenna specialist in Hartford, CT area. The task is to install four rooftop 1900 mHz GSM directional antennas, each aimed at a different base station. The person needs to have experience in antenna installations and a GSM tester, or a modified handset showing BS numbers and signal strength.

Howard, I think you control the high-ground of futility.
I was using an IBM keypunch machine (literally the size of an office desk)
circa 1966 to create Fortran fun. But I only heard legends of people
punching cards with a hand-held punch, and to think you were using a stylus.
Why, that must have been before Xacto knives were invented!

I realise this isnt what you are after....

There is shareware s/w around for turning on the "Net monitor" function
of a Nokia phone. This shows signal strength and all the base stations.
I assume there will be similar software for other phones.

The s/w I know of is "logomanager"

Cheers Bob

Well, I find it hard to believe that, in a weak moment, I visited the site mentioned below. It is obvious that a great deal of time and effort has gone into this thing, and to what cause? To save our rights? Me thinks not. What rights are we having trampled? You're right to slander RadioShack? That right is only in your mind. You are most likely a relatively well educated individual with many personal conflicts in his life and I feel deeply for you, but mostly your parents and family members. They most likely put up with your drivvel year after year and detest the site of you.

Why don't we just cut to the chase, and you explain, in a very short sentence or a very, very short paragraph what caused you to create this Radio Shack site that you claim sucks so bad that it has obviously destroyed your life and those of your loved ones? When They haven't harmed you. You are harming them by saying to the world that they suck.

I have enjoyed Radio Shack for many years. I was there when they became RadioShack, and I became a valued customer (I believe that because I still get free catalogs in the mail, not many do anymore 'ya know) to them and grew through the whole gammit of stuff they have added over the years and I must say that when I had a problem with a product, and that was extremely rare, they took care of it. In one case the manager returned my money because it was a last item and he couldn't replace it. A few years later when computers came along if this had happened, they could check all the stores in their system to see who still had it on the shelf and that store would mail it to me at my home. Is that cool? I say "Yea Verily".

I love Radio Shack. This little reply is probably enough to get you to open up KF5DEsucks.com I won't sue you unless you get nasty. All my friends will check in and post there I'm sure they will have comments to make there, they have a lot of freee speech to use 'ya know. I have a friend that can enlist, in moments hundreds of hackers that believe in not only free speech but free hacking tooo!! Free viruses', free wurmzs, 'n free other stuff too.

After that you can open up another site, KF5DEreallysucks.com

Or, you can channel your efforts into something productive and usefull and possibbly profitable for yourself and your suffering family which will no doubt heal many open wounds.

Butch Magee, KF5DE
Diamondhead, MS 39525

With power on or off? If they can do it with the power on, they might
just have a chance of getting BPL to work.

Naah! Why did I say that? May BPL die an early and well deserved death.

Hi Leland,

They may work fine, but having an answer does not make it accurate.
You clearly state this on your own further down the page in your
response (I shan't duplicate it).

>> I suggested the use of an impedance bridge and
>> explained the reasons why the frequency was important.
>
>For checking capacitance in general the answer is no, unless the dielectric
>shows extreme variations verses frequency and has a high loss tangent.

However, this is one component you have not measured, and admittedly
so. It also begs discussing other sources of failure that go
undetected. Extrapolation from 1Khz to 27Mhz is tenuous if not
fraught with large scale error.

> About the ESR, equivalent
>series resistance, which is composed of mainly skin effect on the plates and
>losses in the dielectric, this appears in series with the capacitance and
>simply adds to the resistive feed point impedance of the antenna.

This talks to the difference between having a good match, and having a
good radiator. The two have nothing to do with one or the other. If
you can confine a "bad match" to the points between the ends of a
radiator, the state of mismatch is immaterial (and in fact, most
common implementations of antennas - monopoles, dipoles - do support a
mismatch with a standing wave along their entire length notably
described as the current/voltage distribution). All such antennas
find it quite within their ability to ring with standing waves and be
highly efficient.

>The feed
>point impedance of a typical 1/4 wave ground plane with the radials at 90
>degrees to the vertical element is around 30 to 40 ohms, so a bit of extra
>resistance makes the match look better at the expense of a lower over all
>antenna efficiency.

The "bit" of extra resistance so sought (and presumably to the market advantage) comes to upwards of 20 Ohms by your estimation above. With this logic you could just as well glue the antenna to cardboard, add a resistor and make the same claims. The lower efficiency so casually dismissed runs to 4dB; however, that is at the extreme of your range.

This gracious discarding of power only speaks of the scenario where the "capacitor" of the mount has short leads - but it doesn't. Most mag-mounts have several many feet of cable leading back to the source, which then matches that length through the chassis to return to the opposite side of the "plate" supported by the sheet metal beneath the mount.

If simple math employing mount radius, paint thickness and the like sufficed to explain how mag-mounts "need" their capacitance to appear beneath them; then the same analysis can be applied to the cable that leads to the same mag-mount's plate. I would offer that a simple six foot length of that cable, ordinary rg-58 (shield O.D. at 0.195" with overall O.D. at 0.210"), offers on the order of 40 odd square inches of surface area. Being a cylinder, not all of that surface is in close contact with the chassis as it is routed along to the mag-mount. As such, I will assign it a plate separation distance of half the overall cable O.D. or 0.105". Plugging and chugging through the standard formulas results in several hundred pF.

>Capacitive coupling to the body of the car is required,

So, by the faith of needed capacitance at the mount ("how else would it work?"), we find there is as much (and likely more) capacitance found in the cable leading to it. If the mount's was more than necessary, it would seem the cable obviated it well in advance. Hence, the "need" of this capacitor is practically nil as it already comes free with the transmission line - and let's face it, a six foot line is fairly short.

Really, when valid measurements are replaced with faith-based logic, this argument that there is some virtue in a lossy capacitor is strictly for advertising copy and if it blew away in the wind, no one would miss it (and possibly they would get out further).

Hi Hal,

You've hit the nail on the head. The other howler is when they claim
to have researched old data showing:
>In 1738: 303,320 +/- 310 km/second
What km? There was no such unit of measure then. Of course, they
could have guessed to an accuracy of 0.1% couldn't they? Same with
their watch. I don't suppose it was an Oyster Rolex.

Creationist "science" is so amusing. Seems faith isn't enough
anymore.

Steppir sells a device called the BoomSlide which makes it possible to install or take down the antenna one element at a time. The device clamps to the boom/mast plate and cradles the boom, allowing it to slide forward and backwards. So, you could simply remove the driven element and lower it separately. Since the element mounting brackets are fixed to the boom, you have no problem aligning the individual elements to the boom when reinstalling them.

Ever wonder why so many different types of capacitors exist? I mean,
if the dielectric properties of so many materials had such little
variation with frequency, why the need for so many different types?
Why are mica, air and vacuum caps sometimes preferred for RF over
ceramic? Why not just use electrolytics? Of course you know the
answer, and that's why if you are going to measure a capacitor you
MUST measure it at the operating frequency. And, if possible, under
load.

> About the ESR, equivalent

>antenna efficiency.

ESR is not just skin effect and dielectric losses. But skin effect
-is- a major factor where ferromagnetic conductors are concerned; and
dielectric losses in many materials mount up quickly with frequency.

Regardless, you didn't measure the impedance at operating frequency so
you don't know the ESR.

> Capacitive coupling to the body of the car is required,

That's just flat-out wrong. Except for the inevitable capacitive field
between the radiator and the ground, capacitive coupling is not a
prerequisite for the antenna to operate. This is clearly proven by NGP
antennas, which use a specific length of coax as the counterpoise. In
case you never noticed, most CB mag-mount antennas come with the very
same length of coax already attached, which should give you a clue as
to how mag-mounts are grounded.

>if there is no direct connection, to mirror the 1/4 wave element, thus
>producing the required 1/2 wave element needed for a resonate antenna.
>Losses in the car body material are a completely separate issue and has
>nothing to do with how the coax gets coupled to the car body.

Losses in the vehicle body have a great deal to do with any capacitive
coupling to the body. If the losses in the steel are high (due to
whatever factors involved), the result will be excessive ESR in the
coupling, and the ground impedance presented to the coax is also going
to be high. And unless you have some other way of setting the antenna
end of the coax shield at RF ground you are going to get RF on the
shield.

>Now if you wanted to measure inductance I would say yes because you have
>capacitance between turns that effectively reduces the inductance and since
>the capacitance electricaly apperas in series with it. The same applies to
>measuring coil Q, and that is because of skin effect and proximity effect.

As with ESR, there are many factors that will affect the Q of a coil,
not the least of which is the permeability and magnetic losses of any
material in and around the coil. But what coil? I thought this was
about the capacitive coupling of a mag-mount antenna base?

>> As I said

I agree 100%. And for that same reason you should know that you can't
measure impedance at 27 MHz using a capacitance tester that works on
audio freqs. Not to sound demeaning, but you should have learned that
much in freshman physics.

One issue you fail to consider is the possibility of error because
your measurement 'seems' correct; i.e, it's what you expect to see.
Happens all the time with inexperienced techs.

Hal Rosser wrote:
> - and who's watch are they using to 'time' all this?

The relativistic effects affect all watches. However,
the time drift can be observed by comparing atomic
clocks to Bristlecone Pine rings - they don't match.
The farther back in time they are compared, the farther
apart they appear to be in time.

Seconds are getting shorter. That means the universe
is not as old as we think. We are assuming that seconds
have been constant since the beginning of the universe.
How old would the universe be if each second were half
as long as the previous one?

There is supposed to have been an inflationary phase to
the early universe. What if the inflationary phase never
ceased and we are still in it? That could explain the
illusion of dark matter and dark energy.

A solid power line fault usually causes removal of power
from the section of line exhibiting the fault. However,
automatic reclosure will often clear the fault.

>As such, I will assign it a plate separation distance of half the
>overall cable O.D. or 0.105". Plugging and chugging through the
>standard formulas results in several hundred pF.

Now THERE'S something I haven't tried, so I went out and tried it. I
ended up doing four tests:

1. I cut six feet of RG-58/U and layed it loose in the bed of my S-10.
At 27 MHz it measured 100 pF, and 130 pF when held flat and straight
by putting a 2x4 on top it. Impedance was about 70 ohms and 55 ohms,
respectively.

2. I unplugged both ends of my installed coax (~12' of RG-8/U) and
tested. Measured from the antenna end, capacitance was 390 pF and
impedance a little under 20 ohms.

3. I plugged the RG-8 back into the radio (radio is mounted directly
to the truck chassis on the hump). Again measured from the antenna
end, capacitance dropped to about 310 pF and impedance rose to about
25 ohms.

4. With the coax still plugged into the radio, the GDO was brought up
to the resonance of the coax, which dipped at around 45 MHz (GDO dial
isn't too accurate). Capacitance was unmeasurable and impedance
dropped to about 3 ohms (estimated).

And for the sake of mentioning it, I tested the ground impedance of
mag-mount bases many years ago when I still thought mag-mounts were a
neat idea. The typical measured impedance was several hundred ohms.

Now anyone can draw their own conclusions from these tests, but IMO
they serve to reinforce my previous conclusion that mag-mount antennas
work by using the coax as the ground, -not- any capacitive coupling at
the base. The capacitance at the base may contribute to the ground
when the coax isn't resonant, but only minimally.

Thanks for the idea, Richard.

Hal, the USCG authorizes the USCG Auxiliary to use land-mobile radios on VHF-Marine band. This is commonly accomplished with amateur radio antennas cut for 2 mtr, and even without modification they do a fair job for 5-10 miles using the standard mag-mount design. The radio is typically a standard VHF-Marine unit with 25w output. With the antenna trimmed for the lower end of the Marine band they of course perform a litttle better. I had one occassion to try an alternative to the standard car roof mount last summer. I was stationed on the Chesapeake Bay Bridge Tunnel for an activity taking place, and had a standard Shakespeare coil-loaded 5' marine antenna on the roof of the SUV. It's performance was "poor". When I grounded the antenna to a piece of bridge railing (the bridge at that point between islands was about 4 miles long) the rx & tx improved notably. This extended the range that I was copied loud and clear from 5 miles to over 15 miles. Overall, a typical mag-mount antenna would probably have equaled if not outperformed it. Then again the marine antennas were not designed for car-roof mounting.

I helped a friend put one up. The "elements" are just hollow fiberglass tubes that the copper tape runs inside. To remove an element, you just retract the tape, then unscrew the element from the boom. They are very light and easy to handle. So, you don't need to move the placement to get then out of the way.

the funny story has been around a long time including versions that the
idiot was a mason.

what gives the story a believable element is that every ham radio club i
know of has one individual who has a propensity for doing idiotic things and

then telling the world all about it :)

1236. Impedance mismatch question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-02 16:34:03 UTC
From: Jimmie <Gfender@carolina.rr.com>
Message-ID: <%1uPc.232806$2o2.12640082@twister.southeast.rr.com>
Source record: 91507

Items involved are solidstate transceiver with fixed output impedance of 50 ohms, 50 ohm feed line and vertical antenna with a feed point impedance of 25 ohms. The one thing that can be varied id feed line length. Should the length be adjusted so the radio sees the 25 ohm impedance or 100 ohms impedance or something in between. OK I will go ahead and admit it, this is for a CB in the camper. Dont get road condition reports on 2 meters.

I work mostly in time domain, so I need to convert s-params into
lumped device models, and it would be nice to have some software
(affordable software!) that does that. That's not really "dumbing
down" to me... it's the s-params that are dumb simplifications!

One trick I use is to visually estimate fet input and output
capacitances to see if a device is worth closer inspection. Just run
eyeballs down the S11 angle column and estimate the frequency (in Ghz)
where the angle hits 40 degrees. The reciprocal is Cin in pF. Ditto
S22 for output capacitance.

John

Hi Dave,

So much of those "early" observations abstracted to today are spun from wishes and dreams born of boredom. 100 years ago when scientists were trying to measure the transit time of Venus across the face of the sun, they ran into rather simple problems that taxed their limits of accuracy. The claims of how older studies obtained MORE accuracy with MORE limitations border on the ridiculous.

The theory as it stands in accredited scientific studies could easily account for a change in the speed; however, when those results don't fit the pre-conceived notions of a biblical time-line, we are indulged with a lot of fudging to force fit curves into a secant-squared (?) shape? Such imaginings that the speed of light has only now stabilized for us are narcissistic in the extreme.

Is there any evidence that the period of Earth's orbit has changed
in the past 7000 years? - in the past 2000 years? The spread between
carbon dating and Bristlecone Pine rings is a continuous function of
time so any evidence should be detectable over only a few years.

Hi Paul,

What is more, no one has actually SEEN the earth go around the sun.
We might presume the opposite, if faith allowed that when the sun set
in the west, it was in fact the same sun that appeared in the east.

This leads to another test of faith. The speed of light (or time) has
changed 1.16% since the first reported "measurement" some 260 years
ago. The years were short back then? Hard to imagine anyone would
miss a difference of 4 days.

If we are talking about solar orbits, the test of faith becomes
enormous back in Methuselah's day when the year was roughly 6 weeks
long (or is it the weeks were 30 hours long? Or is it the hours were
6 minutes long then?). Anyway, we would have had to have been in an
orbit inside of Mercury's to make that all come out in the wash. Hard
to imagine no one's noticed (and harder yet to have had any ice ages).

Hi Jimmie,

If that is all you can vary, skip it. No one is going to notice any
difference no matter how long or short you make it. If the SWR
concerns you, add 150 feet of RG-58 and you won't measure that SWR at
the transmitter.

From: krt2054@charter.net
Message-ID: <33d49c4.0408021158.7e19aa44@posting.google.com>
Source record: 91524

I need a temporary quick and dirty antenna for 15m and 20m. I can easily set up a vertical length of PVC plumbing pipe on the ground and bottom feed it. Essentially a bottom fed 1/4 wavelength vertical. I intend to use a galvanized screen material, 1/4" square holes, as the ground plane, lying on the physical Earth ground. Probably about 6 x 6 feet. I do have an antenna tuner. May transmitter output is 100W maximum. Feed line is long, about 75 feet.

Questions:

1. I am going to use a copper clad, steel stranded wire and place it * inside * the PVC pipe. OK? Or would I be advised to string it outside the pipe?

2. In order to shorten the vertical PVC pipe can I helically wrap the radiating element around the PVC pipe? (outside, of course ;-))

3. Does the ground plane screen need to be grounded, to Earth ground?

Thanks.

Thomas

Instead of PVC pipe, you might want to consider a South Bend
SD-20 (ft) fishing pole that collapses to 4 ft total length.
Works well for me.

If the impedance at the antenna is actually 25+j0 ohms, the varying the length of the line will not change the SWR the transmitter sees. The 2:1 SWR the transmitters sees is however not that big a deal.
You could do this: run I meter of RG58 from the antenna. Stick an 82pf capacitor across the coax at the end of the 1 meter of cable. The impedance at this point is near 50 ohms. Attach as much 50 ohm coax at this point as needed to get to your rig. Instead of a capacitor you could use an open ended stub made of 1 meter of RG58. Does the same thing as the capacitor.

Probably be easier to run the wire outside the pvc and secure with plastic wire ties.

> In order to shorten the vertical PVC pipe can I helically wrap the
>radiating element around the PVC pipe? (outside, of course ;-))

Yes, within reason, I would do a fairly loose helix.

>Does the ground plane screen need to be grounded, to Earth ground?

If it is a very LARGE ground screen there may will be enough capacitive coupling to ground. If not, then you will reduce ground losses by grounding.

If you intend to use the vertical on 20 and 15, you will need to feed it with low loss feedline and use your antenna tuner.

I suggest that you put a short length of the pipe
in your microwave oven, together with a glass of water.
Heat on high for a few seconds.

If the pipe is warm, then put the wire outside the pipe.

The ground plane does not need to be in contact with the
ground, although a safety earth spike is a good idea.

Actually that is evidence for one theory (likely fact) that days are getting longer. I sat in on a fascinating presentation by a paleontologist regarding the possibility of a fossil record of this. Seems that shelly animals today actually have micro growth rings that happen on a daily basis. Some fossils have what *appear* to be such a thing, but he is being cautious before suggesting such.

So the fundamentalist creationists try to find "evidence" to fit their preconceived faithnotion.

Why do fundies accuse scientists of Dogmatic thinking when they demand unquestioning adherence to what they proclaim to be true - and all this under threat of everlasting condemnation in what amounts to an eternity of torture and pain.

Haven't heard any scientists making similar "offers".

Finally, if that is intriguing:

Assuming that the great biblical flood happened *exactly* as written in the Bible:

How much water did it take to cover mount Everest with say a foot of water. Assume that the rate of height gain per year was the same at that time.

Even without the calculations, that is one great galloping lot of water.

Where did the water in the great flood come from?

Where did the water in great flood go to?

Finally, did the Kangaroos and other animals in Australia swim to the middle east to get on Noah's ark so they wouldn't drown when the flood came?

Perhaps. I hear bristlecone pine rings have changed. Presumably
they're an indicator of the length of a year. Some say that means that
the length of a second has changed. Others might claim it simply means
the kinematics of Earths orbit have changed. :-)

How ya doin', Cecil?

Jon these same parts are already in your radio tuner
or separate tuner. The capacitors are controlled by a
microcontroller in the tuner.
There is no reason why you should not put these same
parts into your antenna and control them using your
present automatic control in the shack as you change
frequency.

Good idea Art, but at present I only have an FT817 and 706 IIG, both with no tuners. I have plenty of homebrew ATU's, I could make the antenna just for 40m and feed it with open wire and use a tuner. I just like to experiment, I don't need the thing I just like to be different and to see if I can do the job as well as the commercial guys. I guess I could use two radiating elements, one cut for 40m and one for 20m. It would probably increase efficiency.

As for my radio gear, I am soon to order an Elecraft K2-100 so am looking forward to building that.

Snip
What bothers me Chip about declaration of a new antenna is that it is
immediatly laughed at purely because of many past claims that did not
turn out.Thus the thinking that all is known.
There are many things that have not been tried by ham radio operators
so why negative thinking without knowing what the gentleman has done,
you have probably been down this road of thinking yourself.
For instance, there was reference to distributed loads used on a
vertical
which provided various changes to the norm. What is so wrong about
declaring this idea especialy when it is a novel aproach to the use of
distributed loads? Has anybody made such an arrangement, if not you
will
be surprised
Try modeling a spiral coil as a distributed load, first you model half
of
a spiral and attach it to a vertical. At the top of this vertical you
attach a half of a spiral and at the bottom attach another half spiral
and so on.
Thus you have verticals of different lengths each coupled to each
other
with a distributed load which are arranged at different heights
If you haven't heard of this being done would you knock it?
It is to my mind revolutionary in that it transforms a coil that
radiates
into a cluster with distributed loads of a spiral but without the same
mutual coupling of a spiral and replaced with a different coupling.
Remember when one says a shorter vertical with better results it
does NOT necessarilly mean that the electrical length of the radiator
is SHORTER.
So if the inventor say, did the above would it not be revolutionary ?
And can you categorically say his claims are untrue until one
personally

takes the time and models it. Frankly I feel that many would be
surprised if they talked the talk and modelled such a thing instead
of
using the easy road in modelling by using lumped loads which negates
the actual effects of coupling. (But then the term coupling does
upset a lot
of some antenna gurus on this newsgroup)
Regards
Art

I didnt want to do a whole lot to the rig such as making stubs as the thing
will not be used that much and it would be a royal pain to get to the base
of the antenna. Yes I know line length will not effect SWR. I was concerned
whether the lower or higher impedance may effect other things such as
modulation since this is an AM transmitter with the last two stages
modulated. Last time I messed with a CB loading was adjustable and this
would have not be a question. I was thinking maybe it would be better to
underload the TX with 100 ohms than overload with 25.

Well it does give you the values of components immediately and ensures the
antenna
will alway present a 50 ohm load to the radio and at the antenna input
regardles of frequency
and is large enough for a 100 watt input.I have used this method with an
antenna with a bandwidth of 5Khz
where the bandwidth moved with frequency change.
Really helps when you are alongside heavy broadcast signals on top band
where it preserves the noise floor
of the receiver.
Good luck with the experimenting

Mm... No, not this way.
The objective is to let the beam on top of the tower and using the electric
cage to lowering it to the ground
We bought a motorized winch to avoid climbing on the tower.

What determines the amount of time between winters, Cecil? It could be that the length of a second changed, or the distance the Earth travels in a year changed.
In some ways it amounts to the same thing, don't you agree?

> If I could reverse the aging process, I would be doing a lot
> better. H&H are giving me fits.

Sorry you're bothered with that - whatever it is. Would you mind getting a phone call?

Thanks,

Jim AC6XG

Oy! We could either have the length of the year/day/second changing due to mechanical reasons, or we can have a strange concoction of gobbldegook that not very neatly manages to make one fundamentalist group's idea on the age of the universe miraculously "work out"....

Occam's razor candidate for sure!

As reported it is by definition 2:1.

For mobile CB radio just plug in the antenna & radio and have a go.

A 2:1 VSWR is only a 10% mismatch and most CBs will easily handle [i.e.
not self destruct] at 2:1 VSWR.

I recently acquired an old Hy-Gain vertical. I don't believe its in the AVQ series. It has 3 traps (marked 10-15-20), and has a 4 spoke top hat. On top of the top hat is what looks like a Hustler vertical with a whip and a large ball on the end of the whip. Any ideas what kind of antenna it is, and where I might be able to find any manual for it?
TIA,
Terry

Well, let's see. The sun is a nuclear fusion engine converting hydrogen into helium and spitting out all sorts of stuff like energy, corona mass ejections, solar flares, etc. Spitting out all that energy and debris should mean that the mass of the sun is decreasing. If that is so, then the gravitational mass of the sun has decreased. That should mean that the planets have to re-adjust the planetary orbits to achieve force balance.

Now, SOL is one star in millions in our galaxy. And all these stars are active nuclear engines. So I expect the gravitational constants throughout the Galaxy are also decreasing. So, an exercise for the student is to calculate the growth rate of the Galaxy as well as the growth rate of SOL's universe and the growth rate of the Earth's orbit.

Without doing some weird physics calculations, that are beyond my expertise, I can easily conclude that, Qualitatively, evidence exists that the planetary orbits have changed and are even changing today to balance the dynamically changing gravitational force conditions.

Now how to quantify the growth rate of all the various orbits ... that's "LEFT AS AN EXERCISE FOR THE STUDENT', to quote an old physics professor from many years ago. <grin>

Terry -

Could it be the NewTronics/Hustler BTV series, such as the 4-BTV model ??

DX Engineering has the assembly manuals and parts for the Hustler HF
verticals

Yes, I have a model. Did it sometime back when the question came up on modeling a real coil
instead of just using a point load . When you 'close couple' (not mutual coupling) elements
by placing an element INSIDE a coil which means inductive coupling plus capacitive coupling.
one CAN NOT accurately model parallel circuit radiators using point loads.
(Hopefully by now most will understand what I mean by parallel circuit radiators versus series)
When you break up the individual partial or complete coils you are able to control inter-coil
capacitance features. But then surely you have done all this before and thus know the outcome
of such an arrangement as you have ridiculed my antenna over the years and you know everything
there is to know. Actually I was surprised that the gurus did not model a loaded vertical this way
during the argument on depreciating current with constant phase angle on a coil that carried on to
Dayton, but then winning an argument is the requirement on this group not revealing facts.
But that was not the point of the posting. I was to point out that when looking at the future
it is wise to be knowledgeable of the past but not to be blinded by it.
There is a new antenna that
is going to be explained and without any actual technical information available there are only
closed minds regarding its true veracity
Nothing other than a personal observation/comment.
Art

You have a good point - If the earth completes its revolution faster, then time gets compressed
Same thing happens outdoors - The trees bend over in a wind - so to get a windy day, we can use a winch and cable to bend the tree - and the winds shall come

According to the Lorentz transformations, length and time are affected
by velocity. But velocity = length/time.

v' = x'/t' = (x-vt)/[t-(vx/c^2)]

Nope, it wasn't. God created light on the *first* day. He created the sun, moon, and stars on the *fourth* day. After the Big Bang, when the universe became transparent, there probably was a lot of light but no stars yet.

Since God knows, before one is born, whether one is going to end up in heaven or hell, does one have free will? :-)

I suggest 13.56 MHz, but don't use any more power than you need.

I must be missing something here.
You are in a very rural area, so you feel you don't need to comply with
broadcast radiated power restrictions.
You claim the signal never makes it to the nearest neighbor's house.
So what's the point in transmitting, if nobody receives the signal?
Are you doing some kind of subliminal suggestion on the prairie dogs?

> I have searched the web and can't find any information on 75 ohm twinlead.
> Can anyone identify this wire from these dimensions? ...

Hi John,
it is easy to measure the characteristic impedance Zo of any twinlead
or coax, if you have a device to measure inductances and capacitances.
The frequency you measure these parameters on should be close to the
working frequency, but even measurements on 1 kHz give a good
estimation of Zo for RF !
How to do it:
1/ take an arbitrarily long piece of the twinlead, about 3 m (10 ft)
should do;
2/ measure its capacitance C at one end, while the other end is open;
3/ measure its inductance L at one end, while the other end is
shorted;
4/ calculate Zo = sqrt (L/C)

Yes, as have several others. Nothing remarkable noted then by anyone.
Nothing new has been described since. Results between modeling the
literal coil and using a point source barely differed in the final
product (what would be received from such two "different" antennas) by
more than a quarter dB - if that much.

>Actually I was surprised that the gurus did not model a
>loaded vertical this way

As I've said, that was done - fairly early on in fact. There have
been no tests offered to dispute these conclusions and no new models
that have upset conventional wisdom.

So, does your model offer anything new on the horizon?

Actually they have significant loss. It turns out that a t-line with loss
has a complex characteristic impedance, not just resistive, so they have to
match complex Z0 's

Yes I did actually measure the SWR. I was also trying to convey that I was not trying to change the SWR by changing the cable length. I was concerned that of 100 ohms or 25ohms one may be a better load for the TX. After some testing last night and this morning there does seem to be a difference, Modulation is a little better when the TX sees 100 ohms. I suspect there may be even more difference if the SWR were higher. Is this why CB antenna manufactureres recommend using 18ft(3/4 wl) of coax with their antennas. Perhaps there is a little truth to the myth.

Depending on how long the run is from the rig to the antenna, use
either a 1/4 or a 3/4 electrical wavelength feedline made up of
parallel sections of RG-59. It will be Close Enuf.

Andrew:

Faced with your situation, here is what I would do. Put a 100 watt light bulb with the tuner, and add a remote temperature sensor just inside the AH-4, or at least thermally tied to the surface on the side away from the bulb. This can be wired or wireless, although I would use a remote thermistor without any electronics. Carefully wrap the items in several layers of fiberglass insulation, fully covering all sides. For mounting, suspend the "ball" of fiberglass in some plastic straps, near where the antenna exits. Now, before you operate, remotely turn on the light, and wait until the temperature indicator indicates the tuner is above -10° C, and hit the tune button. Be sure there is a remote indicator the light is on, to preclude overheating if left unattended.

Hi,

After analyse using a tower equipped with a electrical cage (lift) to lower the antenna, it seems that there is no solution to lower a 3-ele steppir antenna without moving the central element off the passage what 'd modify its F/B ratio... thus to avoid even if the steppir has to be tune for each band (and frequency).

As we don't want to climb on the tower each time we have to lower the antenna there is no other solution than buying another model.

The door is not close for Steppir, but knowing its high price (over 2x a titanex 7 ele for example), it seems that our best choice is to look at Titanex.
Less than 700 euros vs. 1300, even if the price is not the problem, the gain of a 7 ele 'd be better than the 3-ele steppir or even optibeam. Titanex is also very light (titanium) and not all models are bulky.

So if this is not a "bye-bye steppir", we are not far, this simply because the tower uses a lift...

So the lesson to learn : when you select your tower with a lift, think about twice about the model of antenna you want to place on top.
We don't regret at all the Hummel tower but we have to select your antenna consequently and not the contrary.

Jim

There is a big benefit to someone as ill informed as myself when these
discussions involve guys who are actually informed and present
understandable info for "jump starting" guys like me.
I probably wouldnt have read the posts if I'd started reading only *one*
side, without some kind of contradiction.

Jerry

1318. Lindenblad antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-03 17:24:20 UTC
From: Jerry Martes <j.jmartes@verizon.net>
Message-ID: <8TPPc.1032$P16.1005@nwrddc04.gnilink.net>
Source record: 91439

I think I understand most of how the Lindenblad antenna works. But, I have questions about how to get omniazimuth circular polarization, and wonder how the Lindenblad concept is doing that.
If anyone had insight and/or experience with the Lindenblad antenna design, I'd sure like to learn more about it.

Jerry

He should be cautious. Internal structures of fossils would seem to be quite the contradiction. At least from my simplistic understanding of what fossils are, and how they came to be.

Well, that was Jim yer replyin' to, but since you're not Paul
Burridge, that's perfectly fine and I'm glad you did. It reminds me
that back when that big Canusa (not Canusa TM) happened, the poster
that goes by Ralph and Diane IIRC wrote a nice piece about the
dynamics of power systems, line reactance and all that.

That's a new twist for me. You saying we should slap each other
around some more? ;)

Just to summarize the part that's IMO most relevant to Burridges
learning disability, Chis Bowick, on pp. 105 - 107 of Secrets of RF
Design shows an example of a Z plotted on the Smith chart and he
labels it with the complex number representing a Z load and it's
reflection coefficient, both of which can be read directly off the
chart. He then give conversion equations that can be used to find a
numerical answer.

What bugged me is that it's so easy to errantly think that a rect to polar conversion on the Z would yield an S param when in fact doing that just gives you a polar representation of Z, i.e. |Z| = sqrt(R^2 + X^2) and Z ang = atan(X/Y)

> number of quote ">" characters.

I think I agree with you. The Smith Chart is not frequency dependent. The models regarding RF transmission line impedance do start to break down at "low" frequencies. This has nothing to do with the Smith Chart. You get the same bad answers with analytical method using bad models as you do with a Smith Chart. IOW, Reg was wrong. The Smith Chart is not limited to solving only transmission line problems.

I regard polar numbers as complex, especially if the angle is not zero.

Of course; polar format is just one way of writing complex numbers.

Indeed. There are only certain fossils that are applicable to this scrutiny. Those are ones that have fossilized in extremely fine sediment, where the individual particles are small enough to preserve the detail after replacement, and the rare fossils in which the nacre itself has managed to survive all this time.

1327. HF/6 meter duplexer? Anywhere?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-03 20:52:19 UTC
From: Ken Bessler <kg0wx@NOSPAMyahoo.com>
Message-ID: <2nac7rFudi8rU1@uni-berlin.de>
Source record: 91448

I've been looking (not too hard - been busy) but does anyone know
of a source for a HF/6m duplexer? I want to go from my FT-857D's
HF/6m output to two different antennas - one for 6m only & the other
through a Z100 autotuner to a Van Gorden "All Bander".

Both antennas work good and the 6'er (an inverted V) dosen't need
a tuner. Yes, I know - the Z100 will go to 6 meters but at only 50w
and when I push it to 50w all sorts of wierd things start happening. So,
I built a monoband 6m inverted V.

Right now it's like this:

Rig
coax jumper
MFJ 860 1.8-54 mhz swr/pwr meter
coax jumper
MFJ 1702B 2 pos. ant switch

From the switch you either go directly to the 6 meter antenna or
via the other position to a Z100 autotuner then on to the Van Gorden
All Bander.

The setup works pretty good except when I forget to switch to the
6m antenna and try to tx on 6 with the Z100/All Bander - then all
hell breaks loose! RF in the shack big time! Hell, even my PC shuts off
so bad I have to reset it's power supply via the rear switch. Yeck!

That can't be good, long term wise......

On another thought - has anyone had any luck coating the inside
of the Z100's plastic case with Caig's CalKote copper spray? If
it works 1/10th as good as thier "DeOxit" contact spray, I'm gonna
have to get me some....

Both or more. As Jerry states, these threads are of interest to all
general readers, I copied a couple of posts to the saved folder for
later perusal. So please don't let PB's bad behaviour discourage them.
I only suggest that PB be ignored when he flies off the handle and
starts dissing perfectly good replies because they're not what he
expected or he doesn't understand them. Somehow he manages to generate
huge threads of inanities and then gripe about wasting his time :-)

Cecil Moore <w5dxp@hotmail.com> wrote in message
news:<410f0a95$1_1@corp.newsgroups.com>...
> Mike Coslo wrote:
> > Right, that's how I understand it. But what about the
> > people that know that the flood covered the entire earth?
>
> If you had been living on the shores of the fresh water Black Sea,
> you would also have reported that it covered the entire earth.

Mike and Cecil:

Sadly, you, like millions of others, have been misled on this topic.
Alas, there was no "Noachian" Black Sea Flood, and
the science in William Ryan's and Walter Pitman's book
"Noah's Flood: the event that changed history" has in
several cases been superceded by better information that
indicates that there was no such event, and was in most
cases preceded by evidence that indicated that there was
no such event.
Ryan and Pitman set out to overturn the orthodox view of the
history of the Black Sea, but they have apparently abandoned
their hypothesis, if more recent articles co-authored by Ryan
are any indication. The orthodox view has prevailed, subject
to some recent modifications.

There is evidence that there was an _outflow_ southward
from the Black Sea through the Bosphorus into the Mediterranean
from more than 10000 years ago
(well before Ryan and Pitman's initial 5600 BCE flood date),
continuously until the present day, though there may have been
a relatively short interruption.
And evidence from the south shore of the Black sea shows that
the level of the Black Sea was only 18 m below the present level
at the time of the supposed flood.
The more recent claim by Ryan puts the flood date at 8400 BP,
or about 9000 years ago, but then the "floodwaters" through the
Bosphorus channel would have been only about 5 metres deep.
9000 years ago is when everybody else always thought that
Mediterranean saltwater first entered the Black Sea. At about
that time, the last phase of Glacial Lake Agassiz, in central
Canada, finally found an outlet to the sea through or under the
remnants of the Laurentide Ice Sheet, and so out into the North
Atlantic, raising sea level an appreciable amount, and _perhaps_
triggering a sudden inflow of saltwater into the Black Sea basin.
But probably not sudden or great enough to inspire a Noachian

Flood myth.
Better candidates are widespread inundation of low-lying parts
of the Persian Gulf associated with the final draining of Glacial
Lake Agassiz, and similar flooding of the Tigris-Euphrates delta,
and (most likely) simultaneous flooding of the Tigris and Euphrates,
which would have looked like a flooding of the entire world from
the viewpoint of a person near present-day Baghdad. These candidates
could each or all have inspired the flood myth in the epic of
Gilgamesh, which predates the first known appearance of the Noachian
Flood myth.

Check this out, for a layman-friendly synopsis of the refutation:

http://home.entouch.net/dmd/bseaflod.htm

On the draining of Glacial Lake Agassiz:

http://cgrg.geog.uvic.ca/abstracts/PerkinsOnceDuring.html

Full article:

http://www.highbeam.com/library/doc0.asp?DOCID=1G1:94334735&refid=ip_encyclopedia_hf&COOKIE=NO

And here's a fairly recent news item on refutation of Ryan's
and Pitman's hypothesis:

http://www.charlotte.com/mld/observer/news/4949335.htm

<BEGIN QUOTE>
January 14, 2003

Scientists are seriously challenging a recent, fascinating proposal
that Noah's epic story -- setting sail with an ark jam-full of animal
couples -- was based on an actual catastrophic flood that suddenly
filled the Black Sea 7,500 years ago, forcing people to flee.

In a detailed new look at the rocks, sediments, currents and seashells
in and around the Black Sea, an international research team pooh-poohs
the Noah flood idea, arguing that all the geologic, hydrologic and
biologic signs are wrong.

Little that the earth can tell us seems to fit the Noah story, they
say. The new research takes direct aim at the work of two Columbia
University geologists -- William Ryan and Walter Pitman -- whose
proposal in 1997 ignited much new interest, and much new research,
into Middle East history and geology.

<END QUOTE>

And here are a couple of scientific papers:

"Is the abrupt drowning of the Black Sea shelf at 7150 yr BP a myth?"

http://lava.tamu.edu/courses/geol101/herbert/docs/BlackSeaFloodCritique.pdf

"Persistent Holocene Outflow from the Black Sea to the Eastern Mediterranean Contradicts Noah's Flood Hypothesis"

http://www.geosociety.org/pubs/gsatoday/toc0205.htm

Oh, and lately some Turks have come to the conclusion that there was no Bosphorus Strait until about 6000 years ago, well after Ryan and Pitman would have had their damburst.

There's lots more, but you'd need access to scientific journals to read it; you could ask me for more details if you want them. Some of the articles are available on the Web.

Sorry to splash water in the frying pan.

That was me, but I wasn't seriously suggesting they did break down.
Just having a gently sarcastic prod at Reg's lofty, generalised
dismissal of the usefulness of the Chart.

>Are you doing some kind of subliminal suggestion on the prairie dogs?

Power restrictions are in place to prevent interference. If I'm
a couple of miles from anybody and transmit with 200 mW instead
of 100 mW, I don't see a big problem.

The point is that I can slip a small FM receiver in my pocket, put
on some earphones, and listen to whatever I want to while I'm out
in the pasture, in the barn, in the shop, or wherever else. (Why
would I want to broadcast to the neighbors anyway? My ego isn't
that big.)

We have coyotes, foxes, deer, bobcats, and wild turkeys here, but
no prairie dogs.

1342. Re: Update on DLM Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-03 23:48:28 UTC
From: aunwin@insightbb.com
Message-ID: <85ed38d.0408031548.543bd7df@posting.google.com>
Source record: 91463

Well it all depends as to what you find interesting
What interests me does not interest a lot of people.
Since my top band antenna is now 'laid to rest' I gave
myself a few moments today to design an antenna for 144 MHz
using a minimum of three verticles clustered within
a four inch radius column using 1 " dia aluminium tubing
with a total height of 54 inches high.
No big deal about those dimensions as I was not
pursuing any optimum other than resonance.
Ohmic value was high at resonance thus needed a 4:1 balun
to get it down to 50 ohms(tho I did see 50 ohms resonance at some odd frequencies).
Antenna to be on perfect ground and fed at the ground level.

Results were as follows:

Frequency bandwidth (2:1 swr) was 105 MHz thru 149 MHz
Max gain 9.8 dbi
Max F/B 9db
Lowest gain 4.35 dbi

Pattern varied but generally gain was at horizon
Now there was no optimisation for say 50 ohm feed
gain, bandspread, or front to back and as I said, I
used a minimum cluster of three verticals and only
half coil at vertical end connections.
All of these values can be made better depending
on requirements.
Now I find this sort of thing "interesting" as optimisation
can take different forms INCLUDING making the O/A length
shorter. Now I know that all of the gurus have done this
exercise but because it is not in the books us newbies
have to go our own way and experiment for ourselves.
Ofcourse we don't always share things on the group because
of the hassles that emanate from the gurus. But I for one
believe that 'all is not known', that everything has not been
tried and I am having a ball making small horizonal and
vertical antennas for all the bands using my own designs
without feeling the need to crow about my succeses.
Thus one should see why such a person as I would show a great
interest in what is described as "revolutionary" by an East Coast
experimentor.
Happy experimenting
Art
(For those that are interested, I used an enclosed circle of
around 8" dia with the circle calculations divided into

20 segments and I only used 1/2 of a circle/coil winding at
each vertical cluster ending .Don't waste you time with coil
pitch as it makes things unnessesarily complicated Positioning
of these half coils both vertically and degree wise and vertical
cluster are the prime contributors for optimisation .
Computor program used AO Pro by Beasley For those using other
type programs set the first vertical/coil connection at the top,
second one at the bottom, third next to the top e.t.c
and this will get you in the initial ballpark)

I changed to Activ8 after someone mispelled it. I thought it was a
more proper way to convey "activate" as opposed to "active 8". I got
tired of looking at it and stuck the "e" back in there.

Active8 - when I throw the switch, it works.

Just the polar conversion part which I recanted long ago - probably
in my second post. I haven't reversed my original statement that the
Z can be read as S directly off the chart *as is* if you measure the
vector and project it to the unit circle. The equations on p 105 are
irrelevant to the original question.

> It's about time. I can see
> where you f*cked up, Mike. I eventually got to the bottom of your

That ain't the case. I was looking at the chart and suggested a
polar conversion, which I later termed a "knee jerk" response.

> Anyone can make a dumb-ass
> mistake like that, but it takes a *man* to admit it and apologise for
> going off so rudely on half-cock.

I slapped you around because you couldn't just accept that the
graphical solution works. Also, you're slow on the uptake (remember
not understanding those colored arcs you posted) and it might just
be possible that serious electronic design (as opposed to twiddling
values in spice) isn't for you. I'm one of those assholes that isn't
satisfied until I can derive the design equations from basic
principles and all that. Despite the work required to aquire that
ability, I keep at it until it's second nature.

Thierry,

I am not familiar with your tower, but gather that the cage comes down the side. Isn't there some heading of the antenna that would let you do this? Maybe rotated 45 degrees to the tower face, with the boom fastened to the side of the mast away from the tower. I wonder how accurate your 50 cm number was. Could it end up beong 5 or 10 cm?

There is the "Band" output - a voltage on a pin on the ACC jack that varies
on which band you select. It would, of course be simple to build a
comparator
circuit that makes the simple logic step:

If A => Band then Relay = on else off.

Problem is I'd have to build the enclosure, with the comparator, power
supply
relays and a connection to the ACC jack which, by the way, is currently used
by my W4RT One Touch Tune (for the Z100). The OTT is really sealed good
so breaking into it to tap the line would be impossible. So, I'd need the
following:

Din Plug
Din Jack
Breadboard
1.8-54 mhz 100 watt rf relay
Comparator
power supply
Sheilded case
Ferrites
Misc parts & components.

Whew!

I'd much rather have a duplexer....easy.

Of course if all else fails, I'll just keep on using my 2 position ant
switch.

In the time it took you to type this in you could have gone to aesham.com
and found the duplexer you need . Forgot the brand I have but the one I
have seems to work ok to split off 6 meters for me.

It is a Comet CF360. It may have fooled you as it is marked to go from 1.3 to 30 mhz and then from 40 to 470 mhz. That means that even though you do not need it, any frequency above 40 mhz up to 470 mhz can be used on one port and any ham band below 30 mhz can be used on the other port. You can get them with coax leads and connectors or just the conectors on the duplexer if I remember correctly. That is where a A or B will come after the 360. I think the price was about $ 70. I think I payed about $ 30 for a used one at a hamfest several years ago.

Those modles will not do the split that was asked for . The Icom puts out
LF to 6 meters one one connector and 2 meters up on the other connector. He
wants one that will split 30 mhz and below from the 6 meter band.
The ones you listed will not do the splits.

I've used an older part, the Comet CF-360 on my 706 for a number of
years. The ports are marked 1-30 and 49-470. I ran it on a network
analyzer at work some years ago, and seem to remember the 3db points
being around 42 MHz.

With a few radials (I used 10, none of them longer than about twenty feet)
it is a very nice antenna for 80/40/20/15/10. I used one for quite a while.
Wish I hadn't sold it!

On the Z-100 thought,
I had a problem using a Z-100 near a computer monitor because RFI was getting into the HF and 6m receive through the plastic Z-100 case. I had a roll of self adhesive copper tape on hand and coated the entire inside of the case and it pretty much cured the RFI problem. Now only 6m has a slight increase in noise compared to the Z-100 out of the circuit. I think anything you can do to shield the Z-100 case is a step in the right direction.

1361. Total set up for sale! MA55, yaesu G-800, SteppIR

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-04 06:36:22 UTC
From: specialist <callme@yahoo.com>
Message-ID: <Gt%Pc.202737$a24.186157@attbi_s03>
Source record: 91382

Greetings!
Please contact me if anyone is interested in purcasing the total set up or separately:
Tubular Tower MA-55 with 11 ft extension
Yaesu Rotator G-800 DXA with all the cabling
SteppIR 3 ELE with additional 6m element
RF and Control Cables
Even K-2 has to go.... I LOVE the equipment and I won every competition in NW region that I entered QRP. Placed top 10 in the country and world.
Everything is in excellent condition and working order. Everything is just over 1 yr old. My wife decided to buy a new hose in one of those restricted developements.
I am located in Bellevue, WA. Please contact me by e-mail or check the pictures on the web page www.qrpclub.com
work number 800-627-6982

Hi Tam,

Here is an image during the building of the Hummel tower
http://www.astrosurf.com/lombry/Radio/tower-section-ginpole.jpg
As you see the mast is at left.
We thougth to rotate the antenna of 45 deg to move teh central element away
from the tower but its is difficult
If we install a 3-ele beam, in almost all cases the central element is in
the passage when lowering the beam.
We have to move the central element of about 50 cm or so to the parasitic
elements (the tower width is 50 cm, 20") to prevent this problem.
Steppir as well a 4 element beam but the boom is huge, 10m I think, and no
really cheap...
So up to now we have no solution without modifying the F/B ratio of the
beam, or to look at another brand... easier to handle and cheaper.

Thanks, Mike - I'm aware of that issue - kinda wish I still had my trusty
Z11
but then my FT-857D would smoke it, literally! My PC makes enough noise,
what with the covers removed so a box floor fan can blow air through it -
it's
a very high end machine and even with 4 case fans, 2 CPU fans, 1 coproceser
fan, 2 video fans, 2 fans on each of the three 250g hard drives and intake &
exhaust fans on the 500w power supply, I was still getting MB temps around
145 deg F and CPU temps around 148 deg F. I took off the case covers and
placed a big honking box fan blowing air cross wise through the whole
system.
That did it - CPU temp now 106, PS exhaust temp is 6 degrees above ambient
room temp..

Caig industries has a lot of neato products for electronics nuts like me - I
use
thier "DeOxit" contact cleaner on everything from PC connectors to my
model railroad - 'stuff is great!

They also make a copper conductive coating paint:

http://shopping.netledger.com/s.nl/c.ACCT113328/sc.2/category.182/it.A/id.1632/.f

I've heard of several OM's using this to coat and sheild the inside of the
Z100.

I'm not 100% sure where you are going with this thing, Daryl. As to
the exact details of when a flood happened, I'll leave that to the
experts. From what I can gather from the articles, the point is that
Ballard didn't find the elusive "farmer". He does note that they found

an ancient shore, and the story notes that scholars agree that a flood happened, some say catastrophically, some say gradual. My whole premise in this is that whatever happened, there was no flood that covered the entire planet so that no dry land was left.

Hi Mike,

History is written by the survivors, as the saying goes and where
there were floods, there were flood myths. However, one may discern
an exception to this rule in that these myths were oral long before a
written tradition was invented.

Being oral, they are undoubtedly Ice-Age originated. Here in
Washington/Montana/Idaho/Oregon, we had our own Great Flood. The
Glacial Lake Missoula filled behind the ice dam of the southern extent
of the polar ice cap. When the hydrostatic pressure at the bottom of
the lake at 2000 feet deep with 500 cubic miles of water behind it
broke the dam, the water washed out the eastern half of Washington and
carved the Columbia gorge between Washington and Oregon (also creating
the Willamette valley).

The outflow at the Montana end was about 8 to 10 cubic miles of water
per hour. Further toward the Columbia Gorge (which was stripped of
all topsoil to a level of 600 feet), temporary 1000 foot deep lakes
were created as the scabland plains area drained at a more sedate rate
of 40 cubic miles a day. When the lake emptied, the Arctic cap
re-asserted its closure at the mouth of the valley and the lake filled
again. Then it drained catastrophically again. This happened between
25 and 40 times!

This all began about 16000 years ago when human migration has been
confirmed to have been occurring in this vicinity. Needless to say
this predates writing, and given that the written tradition in this
region has been destroyed by weather over the centuries, that avenue
has been tenuous as a record.

Who knows, if the record had survived, there would be a Hiawatha story
of the great canoe. American Indian culture could have thrived and
moved their religion eastward to indoctrinate the heathen tribes of
Europe and today we would all celebrate communion with Peyote buttons
and Mescal.

Message-ID: <1d2437b33f0921c591c7953c98063ce4@news.meganetnews.com>
Source record: 91389

Hi all,

I have limited space for an antenna, and in order to get any height, it has to be an inverted vee configuration. I have enough space to put up a full-length 40m inverted vee, with the center about 22 feet up.

But if I feed it with coax, it will ONLY ever be a 40 meter (and 15 meter) antenna - since I only get ONE antenna (sayeth the XLY), that will limit my band access.

So what if I still put up the VEE cut for 40m, but feed it with a single wire attached at the center, then to my tuner's single-wire input.... would that still be easy to load on 40, while allow the tuner to load it on other bands?

Comments?

Dave

Hi Mike - I have a nice tuner I'd like to keep using - it's a Kenwood AT-180 but alas it doesn't have a balanced wire input - only coax and single wire. What about running ladder line down the house, then to a balun in a box on the outside to a very short coax to the tuner?

And yes, I think antennas are attractive :-) I'm sure I'll get more antennas as time goes on - it's a brand new house, so she's a little touchy still :-)

Dave

1370. Two dipoles on one feed line?

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-04 18:30:01 UTC
From: Dave <Devarim@hotmail.com>
Message-ID: <71e36daf66252ade5994154dc5b5b606@news.meganetnews.com>
Source record: 91392

Question related to my other post:

What interaction would there be to feed a 40-meter
dipole and 20-meter dipole with a single 50-ohm coax
cable? That way I'd get 40, 20, and 15 all on one cable...
Seems it should work - on the resonant antenna will load,
but I'm sure the lengths would need to be slightly different
than a single dipole on the coax feeder.

Also, what if I were to short out the coax as an option,
and try to load the entire thing using the single wire
terminal on my Kenwood tuner?

Thanks!

Dave

Put up as much wire as you can in your V, and feed it with ladder line and a tuner. A single line to a V is not the way to go.

Your V will split in the middle, and each wire from the ladder line will go to one of the wires at the split. This will work multiple bands. I'll probably catch flak on this, but MFJ makes some nice inexpensive tuners that are great to start out with.

You'll have one antenna, and the wife will be content. Okay, you'll just have one antenna. But when you want to put up more - and you will - just tell here you are thinking about ditching Ham radio, and taking up a new hobby..... hanging out at bars and carousing with lowlife. Too many S.O.'s seem to be *way* too obsessed with how "ugly" sntennas are. I personally find them to be beautiful, slender pieces of art.

Answer #1:
Nope, perhaps.
You describe (sort-of) a top loaded (with two 32 foot wires), 20' vertical, where some of the vertical is probably inside your shack. The tuner may be able to tune it on several bands if you don't mind warming the cockles of your heart.

I use my 40M inverted Vee (@ 35 ft.) on 40, 30 15, 17 (Even talked from Illinois to the Carolinas on 75, but not well). It IS fed with coax & a tuner. Is it great? Don't know, but I've worked Europe on 17 and the US on 40, 15 & 17.

A more popular and probably better option is to feed it with balanced line (300 or 450) and a balanced tuner. Actually, once you have the feed & tuner, you could then make it longer (whatever space you have) and possibly get better performance on 75 & 20 & 10. I say better on 75 due to the increased length because it is closer to a 1/2 wave and on 20 & 10 because the feed point impedance at the center will come down some since the halves are not exact multiples of a half wave.

I had run EZNEC on such a configuration a few weeks ago. What I have is:

1. a 20 m flat top dipole at 40 feet of length 34.1 feet.

2.A 40m inverted V, 66.8 feet long, supported by the 20m feedpoint, and
sloping down at 30 degrees.

The SWR is about 1.1:1 at 7.15 and 14.25. (The second dipole lowers the
impedance from 75 Ohms)

If you do this, you have to trim the 40m antenna first. I presently have a
40/17 m version of this up and working.

Well Howard, I just commented on the machine. But, how it was used also contributed to the problems ... we were punching and reading metallized mylar tape, not paper. Noise and wear and tear are not always the sole responsibility of the machines we use.

The USAF wanted 'permanent tape' [for whatever reasons].

Another alternative is to make that dipole a trap dipole. I made one that covered 40, 20, 15, and 10 Meters. It was coax fed and did not require tuning when switching bands. It ended up being shorter than a standard 40 Meter dipole because of the trap shortening effect. They are a little difficult to tune initially but once there is no more work. OK, except for putting it back up again when the wind blows it down. But we won't go into that.

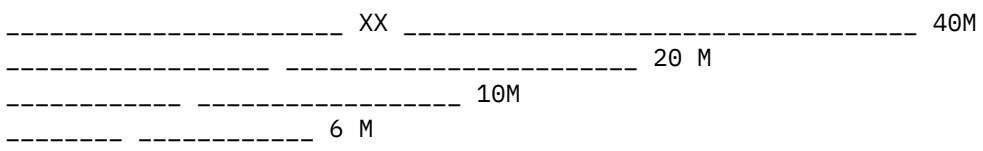
Dave- think be better off useing Flat rotor wire- to your coax. There was an article many years ago, in QST, I believe, that detailed what I describe : Run 2- 33-1/2 foot pieces (40 meter length) of that rotor wire to your end insulators. now, as this wire is 4- inline conductors, strio back 3 of these conductors to 16- 3/4 foot and cut off the excess to the endpoint insulators, now, from that strip 2 of the remaining to 8- 3/8 foot long this will be aprox. 10 meter, the middle would be for 20 meters . If six meters is desired, would be about 55 inchs, from the center for conductor #4, or could do similar for the correct lengths , for 30 meters, 17 meters, and 12 meters! In other words a 4 band dipole, the bulk of wires slightly bigger than a single conductor (about 1/4 inch wide), all in one run. All four wires are connected to the coax-- and the beauty of it is the rotor wire keeps all of them in 1 run! for your consideration- Jim NN7K



4 band dipole

I would get rid of the XYL and put up what you want. But.......if you just
can't do that......

Feed it center fed with ladderline. This to a good balanced tuner, should
do fine. Except on 80 and 160 without some other tricks.

End feeding is not good. Makes lots of RF in the house.

Have had a similar setup for years. Mine is on 40 and 80 meters.

Dipoles are mounted on a PVC pipe sticking out from the top of a 50 foot tower about 3 to 4 feet, horizontally. The antennas run basically north and south.

I put up the 80 running north and south and them pulled both ends slightly off to the west at each end. The 40 was run north and south and then both ends pulled slightly to the east at each end. Hope that makes sense.

Made them both a bit long and then started doing a lot of trimming. Trimmed the 80 a bit, then the 40, back to the 80, then back to the 40. There is some interaction so you can't really just do one and then the other. Used an MFJ Analyzer to check each trim as I went. Can't remember exactly what I ended up with but have been using it for years and it works just fine, no problems. Is there a better way to do it, I am sure there is, but, this is simple and does the job.

>It was a simple, basic question. I gave him the simple, basic, answer.

Well, the original poster did not give height, feedpoint position, ground conditions, surrounding objects ect..
I also think the answer to the radiation angle question should be in degrees above the horizon. If he asked about the radiation pattern of the delta loop, the broadside or end fire characteristics would be a proper response.
My answer (for what it is worth) to the orginal question is : "it depends".
K9SQG has my vote.

That would require a good ground plane as it would essentially
be a vertical antenna with a sloped top hat.

How about feeding the 40m Inv-V with 1/2WL of ladder-line?
That's about 60 ft on 40m. The characteristics on 40m will
essentially be the same as a coax fed Inv-V. And then you
can use it on all the higher HF bands with an antenna tuner.

Yeah, I know what you mean. Here in Canada the forces used the green
metalized stuff as well, although I always thought it was aluminium.
We only used it for stuff like pre-made address tapes where there
were daily messages always going out to the same bunch of stations.
It did tend to wear down the punches a bit, but we used the paper
stuff for regular traffic. After it had done it's job it went into
the Burn Bag, along with printouts, ribbons, used kleenexeseses, paper
coffe cups, chip bags & the occaisional beer bottle (hada love those
field exercises;>).

The computer I originally posted about was a 50's something USAF
design. By the time I got to it in the late 70's nobody had any idea
how it worked, we just had a hand compiled book put togeather by many
many people over many many years saying "If it's doing that, try
replacing this". By that time we were in the process of phasing that
equipment out anyhow, I don't think anybody was sad to see the end of
it :).

Hi Tom,

From Missoula to Astoria basically. Probably 600 miles in the twists
and turns across the Columbia basin out of the Rockies. First a
northwest flow, turning southwest in the Idaho panhandle and then
westerly at the mid-Washington and mid-Oregon border.

73's

The floods also flowed south down the Willamette Valley, leaving car-sized boulders ("erratics") here and there. Much of the rich farmland soil in the valley came from eastern Washington, an area called the "scablands", which is still almost devoid of topsoil.

As Richard mentioned, there were several tens of floods. After the huge lake emptied, the ice dam re-formed. It held until the lake refilled and applied too much pressure, then it broke and the lake emptied again, repeating the process. The high-water marks can still be seen high on the hills behind Missoula. It was one hell of an oscillator!

I have that exact antenna that I've used for years. It's not up right now, but I often take it out for camping/Field Day. Here at home I had it with one leg of the 40 meter dipole horizontal and the 20 meter leg on that side on a slope. The opposite legs were the opposite configuration. This gave it a semblance of symmetry, although I don't know if that made a difference. The trick I used for 15 was to tie in a couple of capacitance hats at the 1/4 wavelength points for 15 meters on the 40 meter dipole, as shown in the ARRL Wire Antenna Classics book on page 1-2. Those were a little tricky to get right, but once set it worked very well on 15. I also have a balun at the center. It's a great antenna - three bands on four wires - and I had great performance and excellent SWR.

73 and good luck with yours,
-- Dave, WA0TTN

The effects of the flood has been documented -
the high water mark caused the ancient ham radio towers to rust up to a height of 40 feet.
the guy wires were washed away, and the towers came tumbling down - right across the walls of Jerry-Ko (the ham's next door neighbor).

"Roy Lewallen" <w7el@eznec.com> wrote in message news:10h38pl9o1542a3@corp.supernews.com...

I have found this thread interesting, but as a Christian minister, I use ham radio as a stresss outlet. Many people hold to deep religious beliefs (including me) and some comments can cause flame wars. Please be respectful of other beliefs, and let's return this thread to ham radio and antenna's. For a discussion of creation and creation science (2 different entities, as creation teaches theology, and creation science focuse on the science) let's move to another forum. BTW not all creationists or creation scientist believe in a young earth, as some hold to an old earth. And not all evolutionists are atheist as some believe in theistic evolution. We have about 8 different systems based around these 2. Check out answers in genesis, and Institute for Creation Research for more info. And too see how the flood could have been global. But, that is a discussion for Sunday's sermon, which is on Creation.

My questions is, if the speed of light is slowing down, then does the wavelength and frequency shift, and if so in which direction? It has been over 20 years since college physics and astronomy...Memory is not what it used to be. If I remember correctly, a relationship exists between speed and frequency. Also, does the speed of radio waves change? E=MC^2 would show that energy is decreasing, which runs counter to the 3 laws of thermodynamics. Where is the missing energy? This could cause a major shift in scientific thinking and laws....Science laws are not absolute. WOW, let me ponder that.

Source record: 91417

NOW AVAILABLE ** New Program "RADIALS2.exe"

This program takes a fresh, revolutionary look at the design and performance of a set of shallow-buried ground radials. Gone at last are the days when 118.5 was a sacred number.

A radial wire is considered as a lossy transmission line, there being no point in having it any longer than that at which its input impedance Zin has converged on its characteristic impedance Zo. The current flowing in the line at that distance from the input end is clearly small enough not to warrant extending the radial any further. With a crude knowledge of the resistivity and permittivity of the soil the greatest practical length of radial wires can be calculated. The number of radials can then be estimated on the logical grounds of economics versus antenna + transmitter radiating efficiency.

Download program RADIALS2, 53 kilobytes, in a few seconds from website below and run immediately.

It's been an interesting evening.
I've made some interesting observations.

I was able to get an Etherwave on a "scratch and dent" sale, that turned out to have a bad solder joint to one of the pitch coils... :) It took longer to take the cover off, than to fix it. But, it was a very significant discount, so I'm a really happy camper.

With the Theremax, the antenna coils were pretty much ignored, and it wasn't clear to me how they should be designed from the information that I've found on the web.

I've been able to measure out what the Etherwave pitch antenna is, using my Tek 7L5 spectrum analyzer, and again the theremin proves to have surprisingly complex behavior.

I'm sure this applies to most theremin designs, as they all seem to have the basic structure of a parallel resonant tank circuit in the pitch osc, and a series LC network in the antenna. I'm sure that some don't take advantage of the behavior that I've noticed here, to their apparent disadvantage.

Conventionally measuring the antenna circuit proves to be difficult, because even the input impedance of a Tek scope probe is way beyond the effects that are produced by operating the instrument normally. Attaching the probe drastically detunes the circuit. Still, with special techniques, it is possible to examine the circuit, relatively non-intrusively. As it turns out, the spectrum analyzer is only needed when you don't already know how to look for this effect, or what causes it.

Background:

The antenna and it's loading coils form a series resonant circuit at some frequency.
I had thought, and now confirmed using the Etherwave, that the behavior of the pitch control would be affected significantly by how the pitch osc is tuned relative to the series resonant point (SRP) of the antenna system.

Most theremin circuits that I have seen, have the same basic structure.
They have a parallel resonant tank circuit in the pitch oscillator, and the antenna and antenna coil form a series resonant circuit.

The parallel resonant pair presents maximum impedance, nearly purely resistive, at it's resonant point. If the antenna circuit was dead on resonant at the same frequency, then it would also present some level of purely resistive impedance.

The interesting thing, is that the antenna circuit presents it's lowest impedance at resonance, and the tank circuit presents it's highest impedance at resonance. So, the oscillator cannot function properly (if at all), if both circuits are tuned to, or nearly to, the same frequency.

What happens:

The behavior of the pitch oscillator is very interesting when tuned near the antenna resonant point. Starting at the lowest frequency, it moves smoothly up through it's range, then takes a sudden jump of about 10-20kHz when we cross the antenna resonant point. Due to the interactions, the resonant point is somewhat indistinct, but we can locate it closely enough to improve the system performance.

Since the pitch oscillator becomes unstable at the point where it hits the antenna resonant frequency, this obviously would be a catastrophic place to tune your pitch oscillator to. :)

So, you get to choose wether to place your pitch oscillator above or below the antenna resonant point. So, I investigated where the range is, relative to this point.
I found that which side you select, and exactly where you select, makes a distinct difference.

I tried a number of points, starting about 30kHz below the resonant point, and ending about 30kHz above the resonant point. Beyond these points, the difference diminishes rapidly, until you have very similar control behavior above, or below the resonant point of the antenna system.

With the oscillator tuned just below the antenna resonance, the control range is somewhat compressed. The closer you get to the antenna resonance, the more compressed it becomes.(!) With the oscillator just above the resonance, the control range is expanded.
The closer you get to the antenna resonant point, the more expanded the control range becomes.

This makes some sense to me from an antenna tuning/tesla coil perspective. On the low side (pitch osc below antenna resonance), the antenna is slightly capacitive. A given increase in your hand capacitance lowers the self resonant point of the antenna, which makes it LESS capacitive, so the tuning range becomes compressed. On the high side, the antenna is slightly inductive, so you make it less inductive and more capacitive as you approach the antenna. These two changes add to each other, and this explains the expanded range. Different antenna and coil designs will react to different degrees, but the basics should hold.

It seems that the shift in the antenna self resonant frequency works in conjunction with the hand capacitance, but only if you are on the high side of the antenna's self resonant point, and fairly close to that point

The coils in the Etherwave are still a compromise, being physically very small, and having a lot of parasitic capacitance. I'll be looking at that soon.

This behavior near the antenna resonance may also explain some squirrely behavior that I saw when first setting up the Theremax.

There is also an area of aluminum tape near the pitch antenna. It is interesting, in that this would not present any sort of "ground plane", even at far higher frequencies. I assume it is being used as a capacitor against the antenna, which could be intended to further increase the control range, by swamping out some of the hand capacitance. I'm not sure on this point yet.

Hi Reg,
TNX for more new programs. I find your ham software very useful.
WARNING: The code on your page has probably been tampered with. When I
left-click directly on the RADIALS2 link, I am redirected to a strange
server. When I right-click, the "Properties" seem to be OK, but an
attempt to "Save Target" fails. I had to hand-type the proper path to
RADIALS2.EXE into the MSIE address line, then I got the software.

Ivan,

I do not believe it is anything serious. The only problem I found was
that the link says "Radials2.exe", but the actual file is "radials2.exe"

It is simply a matter of capitalization. Some servers care, some do not.

Ditto the three previous responses.

My two cents worth is that the amount of interaction depends on how near to one another the different dipole legs are.

If you run one dipole north/south, and the other east/west (i.e., 90 degree physical separation between the dipoles) there will be very little interaction.

If the legs parallel one another, seperated with spacers of some sort(or just hanging, one below the other), there will be more interaction.

If the legs are parallel, and separated by about 6 inches, there will be more interaction than if the wires are parallel and separated by about 12 inches. If the wires are to parallel, putting a spacer close to the feedpoint on each leg helps. I've seen articles on twinlead dipoles, but the SWR bandwidth on them must be pretty sharp.

You can multiband the bands that are not harmonics pretty easily. For example, 40 and 20 have more interaction than would 40 and 30, or 20 and 17.

I had a dipole for 80/40/20 up for a year or so. The SWR bandwidth was sharp on all bands, but a tuner could handle it easily. I now have seperate 80 and 40 meter antennas, but use multiband dipoles for 20/17 and 15/10.

QST had a wire yagi article about 2 years back based on three dipoles for 20/15/10. I built one for just 15/10, works great, and I can pull the dipole off quick if I need to.

Experiment away, but its easier to tune a multiband dipole for SWR in its final location. Lots of FB antenna fun.

Creationists invariably believe in "First Cause". But there is a
logical fallacy associated with such a belief. If "everything that
exists" has to have a cause, then God (as part of "everything that
exists") has to have a cause. And the cause of God has to have a
cause. And the cause of the cause of God has to have a cause ...

Or if one asserts that God is the exception to the "First Cause"
premise, then why couldn't the universe simply be an exception to
the "First Cause" premise?

Who said, "If God didn't exist, it would be necessary for man to
invent Him."?

Candidates must have superior communication skills

Boutique management consulting firm in downtown Chicago needs an advanced-degreed electrical engineer who is highly knowledgeable about 1) antenna design and 2) emerging technologies in the wireless industry. This contract will last anywhere from 10 to 100 hours. The hours will be very flexible. Future engagements may ensue.

The ideal candidate would be an experienced engineer who is familiar with the concepts of MIMO and adaptive phased array antennas. Experience with licensing intellectual property is extremely helpful.

Please submit a resume with a brief discussion of your antenna design experience. For consideration, candidates must have excellent communication skills, both oral and written. Please only respond if you possess such abilities as your skill at articulating complex technical information to the lay business community is crucial.

Again, please respond ONLY if you have excellent communication skills.

rate: $65/hour
please send resume to job-38422472@craigslist.org

>>What did you say your call was .

Welcome to the ARS, Rafael! Congrats on getting your license. Have you joined a club yet? This will be a big step in evaluating your equipment. Depending on the local repeaters, Some may have a feature where after punching in a particular key sequence on your HT, the repeater will record and transmit your signal back to you. That is a really valuable thing.

In the interim between your first post and now, did you ascertain that the audio is low?

One of the first things you want to do is check to see if it is the internal mic, or if it is a gain problem. Buy or borrow an external mic that will work with the unit, then try that. Problem cured? It is the mic. No? then it is probably a gain or other problem.

Hope this helps.

- Mike KB3EIA -

this is a site that oddly enough is a service for blind people, but has many manuals for radios:

1412. Sausage Co-Linear

Newsgroup: rec.radio.amateur.antenna
Date: 2004-08-05 19:08:19 UTC
From: "Airy R. Bean" <me@privacy.net>
Message-ID: <2nff1oFcejcU1@uni-berlin.de>
Source record: 91333
Cross-posted to: rec.radio.amateur.antenna,uk.radio.amateur

Half way through erecting a co-linear for 145MHz, the
Station Manager asked of me what would we be having for
tea?

Being in a creative mood, I came up with the following,
and because of the context, have named it, "Sausage Co-Linear".....

Lightly grease a baking tray.

Make up 6 oz of pastry, but before adding the water,
add and distribute 1 heaped teaspoonful of Colman's
Mustard Powder.

Roll out the pastry and lay it into the baking tray.

Take 1 lb of pork sausage meat and break it up into
lumps no bigger than a large bumblebee. Spread these
lumps out onto the pastry.

Liberally spread Mixed Herbs over the sausage meat.

Peel and slice 6 large potatoes (not baking size) and
cover the sausage meat.

Take 1/2 lb of cherry tomatoes, heat in a saucepan
and reduce.

Spread the tomatoes over the pastry.

Gather the perimeter of the pastry together. (Use the
Cornish Nasty style)

Bake at 180 C for 1 hour.

I have some info that may help in understanding the multiple dipole on one
feedline situation. I'm quoting below a portion of a section from Reflections 1
and 2 that I wrote for this particular situation. Here 'tis:

Sec 20.2.2 Stagger-Tuned Dipoles

There is a second method of obtaining multi-band dipole operation that does
not have the undesirable bandwidth limitation of the trap dipole. This method
uses multiple dipoles fed in parallel from the same feed line, and is called
stagger tuning. The length of each separate dipole is 1/2wl for each band.
Hence, each dipole presents a good impedance match to the feed line on the band
for which it is intended and a poor match on all the others. It is an effective
system because none of the dipoles takes power from the feed line except the one
that is 1/2wl at the operating frequency, and thus it is the only one matched to
the feed line at that frequency. The dipoles need not be configured in different
directions to avoid mutual coupling.
As an example, consider a two-dipole arrangement with one dipole cut to
1/2wl on 80 meters and the other cut for 40 meters. With this arrangement, 1/2wl
dipole bandwidth is obtained on both 80 and 40, and in addition, the 40-meter

dipole is also a center-fed 3/2wl radiator on 15 meters, which also presents a good match to coaxial feed lines. Here is how the frequency selection occurs. On 80 meters, the 80-meter dipole behaves in the conventional manner, but the 40-meter dipole is inactive because its terminal impedance at 80 meters is approximately 14 - j1300 ohms. This impedance results in a mismatch of well over 2400:1 on 50-ohm line, assuring its inactivity. On 40 meters, the 40-meter dipole also behaves in the conventional manner, but the 80-meter dipole presents a terminal impedance of approximately 5000 ohms to the feed line at 40 meters, for a mismatch of 100:1. Consequently, this mismatch is also sufficiently severe to result in an inactive 80-meter dipole on 40 meters, especially since the 40-meter dipole is taking practically all the power from the line because of its good match. On 15 meters, the mismatch of the 80-meter dipole is in the same ballpark as it is on 40 meters, assuring inactivity on this band.
In practice, I have found that a good match results on 80, 40, and 15 meters when 80- and 40-meter dipoles are prepared for l/2 operation using the standard length formula.

OK, Reg, good program. To make it even more useful to lazy hams, pick a few (no more than 5) typical examples and list the results in tabular form. Start at salt water and end at dry sand. My experience (and apparently ITU's, judging from their curves) is that there are very few places which do not fit an easily defined category.

Hi George,

That is because it takes more than soil to define the characteristics.
I can show you three identical soils that are vastly different in RF
response. Located in Texas, Minnesota, and Iowa I believe.
Contrariwise I can find 3 vastly different soils that all exhibit
identical RF responses.

I can understand why Reggie is silent on this matter - too much
liability, impossible to forecast, and it doesn't fit into software

Yes, for instance, the following experiment is expanded somewhat
from what he presented.

1W SGCL 1---------------feedline----------------1W SGCL 2
TV RCVR 1 TV RCVR 2

There are two sources, one at each end of a transmission line.
Each source is equipped with a circulator and load feeding a
TV receiver. The two signals are the same frequency but with
different video modulation. TV RCVR 1 receives the signal
generated by SGCL 2. TV RCVR 2 receives the signal generated by
SGCL 1.

He asserts that no energy is transferred in the above experiment.
You have made similar assertions in the past. So how does the TV
signal get from the signal generators to the TV receivers without
any energy being transferred?

I'd would use what I've found to be an effective alternative. Make it an inverted V, feed it with open wire or ladder line, and you have a nice multiband antenna.

We tried the same recipe, but it turned out the butcher had
stuffed one end of the sausages with soy, the other with meat.
When asked why, he replied that because of tough financial
restraints he was having problem making both ends meat!

> any energy being transferred?

Well actually, what I've said before with regard to similar arrangements is energy would be transferred from each source to the opposite circulator load. And that is independent of whether the receivers are present, which in this case would also absorb some energy. Clearly we have energy being transferred in both directions. Besides, two independently modulated waveforms can hardly be considered 'phase coherent'. Wouldn't you agree?

Of course - it's home made - just the way he likes it.

Sadly I thought someone of his standing would have eaten fresh, home cured or sourced meat rather than sausages, as they can often be seen as a cheaper and mass produced 'off the shelf' foodstuff.....eaten by CBers and M3s? ;-)

> Have you finally completely lost it?

Lost what? He's never had it to lose!

Barry.

Also, as an ordained clergyman who happens to be science/engineering
trained and professed, I have refrained from responding to this thread.

Let's move on. Archeology will study the evidence for many years and
many hypotheses will surface. Science is the pursuit of knowledge.
Theology is the study of God. Eventually they will meet.

DD, W1MCE

Ok, I will take it on your word that this situation exists. As an engineer, I would want to know what is different about the 3 "identical" soils that aren't "identical". And the 3 unidentical "identical" soils. There must be something(s) that is(are) quantifiable, or they wouldn't have different responses. Duh.
